Abstract

Word count: 150

Apicomplexan infections cause substantial morbidity and mortality, worldwide. New, improved therapies are needed. Herein, we create a next generation anti-apicomplexan lead compound, JAG21, a tetrahydroquinolone, with increased sp3-character to improve parasite selectivity. Relative to other cytochrome b inhibitors, JAG21 has improved solubility and ADMET properties, without need for pro-drug. JAG21 significantly reduces Toxoplasma gondii tachyzoites and encysted bradyzoites in vitro, and in primary and established chronic infections in vivo. Moreover, JAG21 treatment leads to 100% survival. Further, JAG21 is efficacious against drug-resistant Plasmodium falciparum in vitro. Causal prophylaxis and radical cure are achieved after P. berghei sporozoite infection with oral administration of a single dose (2.5mg/kg) or three days treatment at reduced dose (0.625mg/kg/day), eliminating parasitemia and leading to 100% survival. Enzymatic, binding, and co-crystallography/pharmacophore studies demonstrate selectivity for apicomplexan relative to mammalian enzymes. JAG21 has significant promise as a pre-clinical candidate for prevention, treatment and cure of toxoplasmosis and malaria.

Contribution to the field

We find that JAG21 is effective against actively replicating T.gondii tachyzoites, and previously untreatable chronic encysted bradyzoite brain stage in vitro, and in mice. We demonstrate JAG21’s synergy with a cytochrome b/c qo inhibitor atovaquone against tachyzoites. JAG21 also is effective in vitro against drug susceptible and known drug resistant forms of P. falciparum. JAG21 is effective as causal prophylaxis and definitive cure in a single oral dose of 2.5mg/kg for P.bergehi murine malaria. JAG21 inhibits both Toxoplasma and Plasmodia cytochrome b q1 and has ADMET properties suitable to become a medicine for people. We prove JAG21’s mechanism of action, using enzymology, binding assays, co-crystallography and co cryo-electron microscopy. We discover how it might be further improved, if this were needed. We demonstrate safety and efficacy against T. gondii tachyzoites and previously untreated latent bradyzoites, the form of the organism that is present in the brain of 2 billion people worldwide, lifelong, and against plasmodia. JAG21 treatment of conditional mutant deltaRPS13 and transcriptomics define a metabolically quiescent “persisters”,“stasis” state that is reversible even after substantial periods of dormancy,. This contributes to conceptual and functional understanding of both Plasmodia and Toxoplasma infections and molecular mechanisms whereby “persisters” might be eliminated. Moving toward addressing this question, optimizing treatment , and identifying co-administered companion compounds that may lead to definitive cure for human infections, we created a stable nanofomulated JAG21. Using this new formulation, we determined that oral administration of JAG21 reduces parasite burden after infection of mice with a highly virulent strain of T.gondii.

INTRODUCTION

Malaria results in the death of ~0.5 million children a year, with drug resistance impacting the usefulness of successive generations of new medicines ([www.who.int/malaria/publications/world-malaria-report-2017/en/](http://www.who.int/malaria/publications/world-malaria-report-2017/en/)). The related apicomplexan parasite, *Toxoplasma gondii*, is the most frequent parasitic infection of humans in the world. It plays a significant role in food-born associated death in the USA, destruction of the human retina, and death and illness from recrudescent disease in the immune compromised or immunologically immature (McLeod, Boyer, 2018). It has been estimated that there are 1.9 million new cases of this congenital *T. gondii* infection globally over a ten year period, causing 12 million disability adjusted life years (Torgerson and Mastroiacovo, 2013) from damage to the fetal brain and eye. Toxoplasmosis is an often neglected, untreated or mistreated disease. There are approximately 2 billion people throughout the world who have this parasite in their brain lifelong, some with known, severe, adverse consequences (Delair et al, 2011; Lykins et al, 2016; Wallon et al, 2013). There are possible additional, harmful effects for a substantial number of chronically infected people as this parasite modulates signature pathways of neurodegeneration, motor diseases, epilepsy, and malignancies (Ngo et al, 2017). No medicine eliminates this chronic, encysted form of the parasite. New and improved medicines are greatly needed to cure *Toxoplasma* and *Plasmodia* infections. These parasites often share the same molecular targets for medicines due to a relatively close, apicomplexan, phylogenetic relationship (McPhillie et al, 2016).
Thus, medicine development for each of these parasites can inform development of medicines that benefit treating the other (Muench et al 2007; Fomovska et al, 2012).

One such shared molecular target is the mitochondrial cytochrome bc1 complex that is important for the survival of apicomplexan parasites such as Plasmodia and T. gondii. Cytochrome b is a subunit of the cytochrome bc1 complex, an inner mitochondrial membrane protein that is part of the electron transport chain. Activity of this complex is integral to oxidative phosphorylation and generation of ATP (Vercesi et al, 1998). Cytochrome b activity appears to be necessary for the replication and persistence of the parasite (McPhillie et al, 2016), and is the site of action of atovaquone (McPhillie et al, 2016). Cytochrome b is the target for quinolone-based compounds, but, significant problems with solubility and toxicity have been noted with earlier cytochrome b inhibitors. In an attempt to design novel quinolone-like inhibitors with improved solubility, and lower toxicity, compared to known compounds in the literature, we synthesized a series of tetrahydroquinolinones (THQs). Our preliminary efforts were described in McPhillie et al (2016). We reasoned that the increased ‘sp3’ character of the THQs (i.e. moving from rod-like to sphere-like 3D space) could provide the required improvement in solubility that would allow for optimal pharmacokinetic properties. Molecules with an increased percentage of 'sp3 character' tend to be more three-dimensional, than their planar ('sp2-rich') counterparts. The terms 'sp2' and 'sp3' refer to the shape of their hybridised atomic orbitals, which have trigonal planar and tetrahedral geometries respectively. Flat aromatic rings ('sp2-rich') are ubiquitous in drug discovery campaigns, but molecules with more 'sp3 character' are often more specific for their protein target and can have better physicochemical properties. Further, we reasoned that the larger binding pocket in the parasite enzymes (McPhillie et al, 2016), compared to their mammalian counterparts, would provide room for bulkier substituents to minimize effect on the human enzyme. Within this new series of compounds, we aimed to identify a mature lead compound with both anti-Plasmodium and anti-T. gondii activity.

Our work developed as follows: We recently found markedly increased expression of cytochrome b in the currently untreatable T. gondii bradyzoite life-cycle stage (McPhillie et al 2016). Thus, we set out to develop a compound that would inhibit tachyzoites, bradyzoites and three life cycle stages of even drug-resistant Plasmodia. We sought to do this without a need for a pro-drug as has been needed in other attempts to target apicomplexan cytochrome b (Frueh et al 2017). Our aim was to improve upon the physicochemical properties of naphthoquinones and endochin-like quinolones (ELQs) targeting cytochrome b, including poor aqueous solubility and toxicity (McPhillie et al, 2016; Khan et al, 1998; Doggett et al, 2012; Capper et al, 2015; Miley et al, 2015). The intent was further to provide potential solutions for limitations of other compounds active against apicomplexan parasites (Waxman and Herbert, 1969; Caumes et al, 1995). Our concurrent crystallographic studies also enable better understanding of the interactions between ligand and the binding pocket of the Qie site (McPhillie et al, 2016).

Herein, we have identified a preclinical lead candidate based on potent and selective inhibition of P. falciparum and P. berghei and T. gondii cytochrome bc1 for the treatment of malaria and toxoplasmosis. The candidate compound demonstrates high efficacy in relevant in vitro and in vivo models of the diseases, and has considerable potential for broad-spectrum use (i.e., against T. gondii tachyzoites and encysted bradyzoites and drug resistant Plasmodia). The data which follow present the creation and characterization of this novel, broad-spectrum, anti-apicomplexan lead compound which has promise for definitive treatment of these infections.

MATERIALS AND METHODS
Syntheses of compounds

Synthesis of tetrahydroquinolones (THQs) compounds.
The THQ compounds were synthesized at the University of Leeds as described below. 10 mM stock solutions were made with 100% Dimethyl Sulfoxide (DMSO) [Sigma Aldrich] and working concentrations were made with IMDM-C (1x, [+ glutamine, [+] 25 mM HEPES, [-] Phenol red, 10% FBS)[Gibco, Denmark]). Compounds are shown in Figure 1A. Final compounds had >95% purity determined by high performance liquid chromatography (HPLC), high resolution mass spectrometry and NMR spectrometry. Liquid chromatography-mass spectrometry (LC-MS) and NMR spectrometry were used to determine the integrity and purity of all intermediates. THQ compounds were synthesized as described in schemes 1 and 2, which describe compounds MJM170 and JAG21 as exemplars. Building blocks 1, 8, 9 and 14 were varied to create the complete series (Figure 1A).

Scheme 1. Synthesis of hit compound 7, also known as MJM170 (McPhillie et al 2016).
Synthetic scheme inspired by the route to endochin-like quinolones (ELQs) reported by Doggett et al, (2012).
**Synthesis of 2-methyl-5,6,7,8-tetrahydroquinolin-4-one (2)**

Platinum oxide (0.100 g, 10 mol %) was added to a solution of 4-hydroxy-2-methylquinoline (1, 1.00 g, 6.28 mmol, 1.00 eq) in glacial acetic acid (10.0 mL). The heterogeneous mixture was catalytically hydrogenated under a balloon of hydrogen. After 22 hrs, TLC (10% MeOH–DCM) confirmed complete reaction. The mixture was filtered through celite under vacuum, washing thoroughly with EtOAc (50 mL). The filtrate was concentrated and the resulting residue purified by column chromatography (10% MeOH–DCM) to give the desired product as a pale yellow oil (0.917 g, 5.65 mmol, 89%); R<sub>t</sub> 0.14 (10% MeOH–DCM); δ<sub>H</sub> (300 MHz, CDCl<sub>3</sub>) 1.74-1.76 (4H, m, CH<sub>2</sub>), 2.29 (3H, s, Me), 2.49-2.52 (2H, m, CH<sub>2</sub>), 2.67-2.70 (2H, m, CH<sub>2</sub>), 6.16 (1H, s, Ar-H); δ<sub>C</sub> (125 MHz, CDCl<sub>3</sub>) 19.0 (Me), 21.8 (CH<sub>2</sub>), 22.1 (CH<sub>2</sub>), 27.1 (CH<sub>2</sub>), 112.5 (CH), 122.4 (Cq), 146.4 (Cq), 147.0 (Cq), 178.3 (Cq), 158.9 (Cq), 158.3 (Cq), Spectroscopic data consistent with literature values (JMC, 1993, 36, 1245-54).

**Synthesis of 2-methyl-3-iodo-5,6,7,8-tetrahydroquinolin-4-one (3)**

*Butylamine (6.20 mL, 62.8 mmol, 10.0 eq) was added to a suspension of 2-methyl-5,6,7,8-tetrahydroquinolin-4-one (2, 1.02 g, 6.28 mmol, 1.00 eq) in DMF (10.0 mL). To this heterogeneous mixture was added I<sub>2</sub> (1.60 g, 6.28 mmol, 1.00 eq) in a saturated solution of KI (6.00 mL). After 20 hrs stirring at R.T., a precipitate formed in the orange solution, excess iodine was quenched with 0.1 M sodium thiosulfate solution (10.0 mL). The precipitate was filtered by vacuum filtration, washed with distilled H<sub>2</sub>O and dried (Na<sub>2</sub>SO<sub>4</sub>) to give the desired product as a colourless solid (1.76 g, 6.09 mmol, quantative yield); δ<sub>H</sub> (300 MHz, DMSO-d<sub>6</sub>) 1.61-1.70 (4H, m, CH<sub>2</sub>), 2.29 (2H, t, J 6.0, CH<sub>2</sub>), 2.43 (2H, s, CH<sub>2</sub>), CH<sub>3</sub> under DMSO peak.

**Synthesis of 2-methyl-3-iodo-4-ethoxy-5,6,7,8-tetrahydroquinoline (4)**

Potassium carbonate (1.53 g, 11.1 mmol, 2.00 eq) was added to a heterogeneous mixture of 2-methyl-3-iodo-5,6,7,8-tetrahydroquinolin-4-one (3, 1.60 g, 5.56 mmol, 1.00 eq) in DMF (15.0 mL), and the reaction heated to 50°C for 30 mins. The R.B. flask was removed from the heating mantle and ethyl iodide (0.67 mL, 8.33 mmol, 1.50 eq) was added dropwise. The reaction was then heated at 50°C for 18 hrs. The reaction was cooled to R.T., quenched with water (40 mL). The resulting emulsion formed which was extracted with EtOAc (50 mL). EtOAc layer were washed with water (3 x 30 mL), brine (3 x 30 mL), dried (Na<sub>2</sub>SO<sub>4</sub>) and concentrated to give a pale yellow oil (1.09 g, 3.44 mmol, 61%); R<sub>t</sub> 0.88 (1:1 Pet–EtOAc); HPLC (RT = 1.67 mins); LCMS (Method A), (RT = 1.6 min, m/z (ES) Found MH<sup>+ </sup>318.0); δ<sub>H</sub> (500 MHz, CDCl<sub>3</sub>) 1.49 (3H, t, J 7.0, ethoxy CH<sub>3</sub>), 1.73-1.78 (2H, m, CH<sub>2</sub>) 1.84-1.88 (2H, m, CH<sub>2</sub>), 2.78-2.69 (5H, m, CH<sub>2</sub> & CH<sub>3</sub>), 2.84 (2H, t, J 6.5, CH<sub>2</sub>), 3.97 (2H, q, J 7.0, OCH<sub>2</sub>); δ<sub>C</sub> (125 MHz, CDCl<sub>3</sub>) 15.6 (CH<sub>3</sub>), 22.3 (CH<sub>2</sub>), 22.8 (CH<sub>2</sub>), 23.6 (CH<sub>2</sub>), 29.3 (CH<sub>3</sub>), 32.0 (CH<sub>2</sub>), 68.4 (OCH<sub>2</sub>), 90.9 (Cq), 124.5 (Cq), 158.3 (Cq), 158.9 (Cq), 163.9 (Cq).

**Synthesis of 2-methyl-3-(4-phenoxyphenyl)-4-ethoxy-5,6,7,8-tetrahydroquinoline (6)**
2-Methyl-3-iodo-4-ethoxy-5,6,7,8-tetrahydroquinoline (4, 0.266 g, 0.839 mmol, 1.00 eq), Pd(PPh₃)₄ (0.048 g, 0.0419 mmol, 5 mol%) and 4-phenoxyphenylboronic acid (5, 0.270 g, 1.26 mmol, 1.50 eq) were charged to a R.B. flask under N₂(g). Degassed DMF (10.0 mL) was added to the flask followed by 2M K₂CO₃ (1.60 mL). The flask was heated to 85°C under N₂(g). After 15 mins, TLC (4:1 Pet–EtOAc) confirmed reaction was complete. The reaction was cooled and diluted with EtOAc (15 mL), filtered through celite and partitioned between EtOAc (10 mL) and H₂O (25 mL). Combined organics were washed with H₂O (3 x 30 mL), then brine (3 x 30 mL), dried (Na₂SO₄) and concentrated to give a red oil which was purified by column chromatography (3:1 Pet–EtOAc), to give the desired product as a pale yellow oil (0.235 g, 0.655 mmol, 78%); Rf 0.31 (3:1 Pet–EtOAc); HPLC (RT = 3.08 mins); δH (300 MHz, CDCl₃) 1.04 (3H, t, J 7.0, ethoxy CH₃), 1.76-1.93 (4H, m, 2xCH₂), 2.32 (3H, s, CH₃) 2.72 (2H, t, J 6.0, CH₂), 2.91 (2H, t, J 6.5, CH₂), 3.50 (2H, q, J 7.0, OCH₂), 7.05-7.16 (5H, m, Ar-H), 7.20-7.29 (2H, m, Ar-H), 7.31-7.43 (2H, m, Ar-H); δC (125 MHz, CDCl₃) 15.7 (CH₃), 22.5 (CH₂), 23.0 (CH₃), 23.3 (CH₂), 23.4 (CH₂), 32.7 (CH₂), 23.4 (CH₂), 68.2 (OCH₂), 118.6 (CH), 118.9 (CH), 123.4 (CH), 126.8 (Cq), 129.8 (CH), 131.5 (CH), 154.9 (Cq), 156.5 (Cq), 157.1 (Cq), 157.3 (Cq); m/z (ES) (Found: MH⁺, 360.1973. C₂₄H₂₆NO₂ requires MH⁺, 360.1964).

Synthesis of 2-methyl-3-(4-phenoxyphenyl)-4-ethoxy-5,6,7,8-tetrahydroquinoline (7, MJM170)

Aqueous hydrobromic acid (>48%) (1.00 mL) was added to a solution of 2-methyl-3-(4-phenoxyphenyl)-4-ethoxy-5,6,7,8-tetrahydroquinoline (6, 0.226 g, 0.630 mmol, 1.00 eq) in glacial acetic acid (2 mL). The reaction was stirred at 90°C for 5 days, monitoring by LCMCS. The reaction was cooled to R.T. and the pH adjusted to pH 5 with 2M NaOH. The precipitate was collected by vacuum filtration and recrystallized from MeOH:H₂O to give the desired product as an off-white solid (0.155 g, 0.467 mmol, 74%); HPLC (RT = 2.56 mins); δH (500 MHz, DMSO-d₆) 1.66-1.72 (4H, m, 2xCH₂), 2.08 (3H, s, CH₃) 2.31 (2H, t, J 6.0, CH₂), 2.56 (2H, t, J 6.0, CH₂), 6.99 (2H, d, J 8.5, Ar-H), 7.06 (2H, d, J 7.5, Ar-H), 7.14-7.18 (3H, m, Ar-H), 7.40-7.43 (2H, m, Ar-H), 11.0 (1H, s, NH); δC (125 MHz, DMSO-d₆) 17.7 (CH₃), 21.5 (CH₂), 21.8 (CH₂), 21.9 (CH₂), 26.2 (CH₂), 117.8 (CH), 118.6 (CH), 121.2 (Cq), 123.3 (CH), 123.7 (Cq), 130.0 (CH), 131.4 (Cq), 132.3 (CH), 142.3 (Cq), 143.2 (Cq), 155.0 (Cq), 156.8 (Cq), 175.4 (Cq); m/z (ES) (Found: MH⁺, 332.1654. C₂₂H₂₆NO₂ requires MH⁺, 332.1645).
Scheme 2. Synthetic route to analogues of 7 (MJM170) via route A or route B. Route A is the original route to analogues but is linear and involves a tricky Suzuki step to intermediate 12 from intermediates 4 and 10. Route B allows quicker access to analogues since intermediate 15 can be made in larger quantities and derivatives can be synthesised via the Chan-Lam reaction to give final intermediate 12 by varying the boronic acid 16.

Synthesis of 1-(4-bromophenyl)-4-(trifluoromethoxy)benzene (10)

Copper (II) acetate (0.435 g, 2.39 mmol, 1.00 eq) was added to a suspension of 4-bromophenol (8, 0.414 g, 2.39 mmol, 1.00 eq), 4-trifluoromethoxybenzeneboronic acid (9, 0.983 g, 4.79 mmol, 2.00 eq) and 4Å molecular sieves (0.566 g) in DCM (12 mL) at R.T. A solution of triethylamine (1.7 mL, 11.9 mmol, 5.00 eq) and pyridine (1 mL, 11.9 mmol, 5.00 eq) was added and the reaction was stirred for 16 hrs, open to the atmosphere. After 18 hrs, the reaction was quenched with 0.5 M HCl (20 mL) and the organic layer washed with water (20 mL), brine (20 mL), dried (Na$_2$SO$_4$) and concentrated to give a red oil which was purified by
column chromatography (hexane) to give the desired product as a colourless oil (0.582 g, 1.75 mmol, 73%); $R_f$ 0.58 (hexane).

**Synthesis of 2-methyl-3-(4-hydroxyphenyl)-4-ethoxy-5,6,7,8-tetrahydroquinolin-4-one (15)**

![Chemical Structure](attachment:structure.png)

2-Methyl-3-iodo-4-ethoxy-5,6,7,8-tetrahydroquinoline (4, 0.400 g, 1.26 mmol, 1.00 eq), Pd(PPh)$_3$)$_4$ (0.073 g, 0.06 mmol, 5 mol%) and 4-hydroxymethylphenylboronic acid (14, 0.260 g, 1.89 mmol, 1.50 eq) were charged to a R.B. flask under N$_2$(g). Degassed DMF (10.0 mL) was added to the flask followed by 2M K$_2$CO$_3$ (3.00 mL). The flask was heated to 85°C under N$_2$(g). After 3 hrs, TLC (EtOAc) confirmed reaction was complete. The reaction was cooled to 50°C, diluted with EtOAc (15 mL) and activated charcoal was added. After stirring for 30 mins, the mixture was filtered through celite and partitioned between EtOAc (10 mL) and H$_2$O (25 mL). Combined organics were washed with H$_2$O (3 x 30 mL), then brine (3 x 30 mL), dried (Na$_2$SO$_4$) and concentrated to give a brown solid which was triturated with diethyl ether to give the desired product as a pale red crystalline solid (0.220 g, 0.777 mmol, 60%); $R_f$ 0.22 (EtOAc); m.p. 225-226 °C (EtOAc); $\delta_{H}$ (500 MHz, MeOD-$d_4$) 7.07 (d, $J = 8.6$ Hz, 2H, H-3 & 5), 6.86 (d, $J = 8.6$ Hz, 2H, H-2 & 6), 3.51 (q, $J = 7.0$ Hz, 2H, CH$_2$CH$_2$O), 2.83 (t, $J = 6.3$ Hz, 2H, H-8'), 2.72 (t, $J = 6.1$ Hz, 2H, H-5'), 2.23 (s, 3H, Me), 1.95 – 1.72 (m, 4H, H-6' & 7'), 1.00 (t, $J = 7.0$ Hz, 3H, CH$_3$CH$_2$O); $\delta_{C}$ (125 MHz, MeOD-$d_4$) 164.0 (Cq), 158.1 (C1), 157.4 (C3), 156.1 (Cq), 132.2 (C-3 & 5), 129.1 (Cq), 127.9 (Cq), 124.9 (Cq), 116.2 (CH), 69.1 (OCH$_2$), 32.7 (CH$_2$), 23.9 (CH$_2$), 23.4 (CH$_3$), 22.9 (CH$_2$), 22.3 (CH$_2$), 15.7 (CH$_3$); m/z ($ES$) (Found MH$^+$, 284.1664, C$_{18}$H$_{19}$NO$_2$ requires MH$^+$, 284.1651).

**Synthesis of 2-methyl-3-(4-hydroxyphenyl)-4-ethoxy-5,6,7,8-tetrahydroquinolin-4-one (12)**

![Chemical Structure](attachment:structure.png)

1-(4-bromophenyl)-4-(trifluoromethoxy)benzene (10, 100 g, 0.30 mmol, 1.00 eq), bis(pinacolato) diboron (1.10 eq), potassium acetate (3.00 eq) and Pd(dppf)Cl$_2$ (0.03 eq) were added to a oven-dried flask under inert atmosphere. Anhydrous DMF (6 mL) was added. The reaction was heated to 80°C under N$_2$(g). After 22 hrs, the reaction was cooled to R.T., fresh PD(dppf)Cl$_2$ (0.03 eq) added, followed by 2-methyl-3-iodo-4-ethoxy-5,6,7,8-tetrahydroquinoline (4, 0.400 g, 1.26 mmol, 2.00 eq) and 2M Na$_2$CO$_3$ (2.9 mL). The reaction was heated to 80°C for 20 hrs, cooled, diluted with EtOAc (20 mL), filtered through celite and partitioned between EtOAc (20 mL) and H$_2$O (20 mL). Combined organics were washed with brine (3 x 20 mL), dried (Na$_2$SO$_4$) and concentrated to give a brown solid which was purified by column chromatography (3:1 Pet–EtOAc) to give the desired product as a colourless oil (30 mg, 0.07 mmol, 23%); HPLC (RT = 2.41 mins); $\delta_{H}$ (500 MHz, acetone) 7.28 (d, $J = 8.7$ Hz, 2H, H-2' & 6'), 7.26 (d, $J = 9.1$ Hz, 2H, H-2'' & 6''), 7.09 (d, $J = 9.1$ Hz, 2H, H-3' & 5'), 7.07 (d, $J = 8.7$, 2H, H-3' & 5'), 3.52 (q, $J = 7.0$ Hz, 2H, CH$_2$CH$_2$O), 2.85 (t, $J = 6.5$ Hz, 2H, H-8), 2.78 (t, $J = 6.2$ Hz, 2H, H-5), 2.26 (s, 3H, Me), 1.89 – 1.81 (m, 2H, H-7), 1.81 – 1.72 (m, 2H, H-6), 0.93 (t, $J = 7.0$ Hz, 3H, CH$_3$CH$_2$O); $\delta_{C}$ (125 MHz, acetone) $\delta$ 161.9 (Cq), 157.1 (Cq), 156.5 (Cq), 156.0 (Cq), 154.5 (Cq), 145.3 (Cq), 132.5 (Cq), 132.0 (CH), 126.7 (Cq), 123.0 (CH), 119.8 (CH), 119.0 (CH), 68.0 (OCH$_2$), 32.5 (CH$_2$), 23.0 (CH$_2$), 22.9 (CH$_3$), 22.7 (CH$_2$), 22.5 (CH$_2$), 15.05 (CH$_3$); m/z ($ES$) (Found: MH$^+$, 444.1792. C$_{25}$H$_{24}$F$_3$NO$_3$ requires MH$^+$, 444.1781).
Synthesis of 2-methyl-3-(4-(4-(trifluoromethoxy)phenoxy)phenyl)-5,6,7,8-tetrahydroquinolin-4-one (13, JAG21)

Aqueous hydrobromic acid (>48%) (1.00 mL) was added to a solution of 2-methyl-3-(4-phenoxyphenyl)-4-ethoxy-5,6,7,8-tetrahydroquinoline (12, 30.0 mg, 0.07 mmol, 1.00 eq) in glacial acetic acid (2 mL). The reaction was stirred at 90°C for 3 days, monitoring by LMCS. The reaction was cooled to R.T. and the pH adjusted to pH 5 with 2M NaOH. The precipitate was collected by vacuum filtration and recrystallized from MeOH:H2O to give the desired product as a colourless solid (25.0 mg, 0.06 mmol, 68%); m.p. >250 °C; HPLC (RT = 2.78 mins); δ_H (500 MHz, DMSO-d6) 11.07 (s, 1H, NH), 7.40 (d, J = 8.5 Hz, 2H, H-3' & 6'), 7.19 (d, J = 8.6 Hz, 2H, H-2' & 6'), 7.13 (d, J = 9.0 Hz, 2H, H-3' & 5'), 7.02 (d, J = 8.5 Hz, 2H, H-2'' & 6''), 2.54 (t, J = 6.0 Hz, 2H, H-8), 2.28 (t, J = 5.9 Hz, 2H, H-5), 2.07 (s, 3H, Me), 1.71 (m, 2H, H-7), 1.65 (m, 2H, H-6); δ_C (125 MHz, DMSO-d6) 175.7 (Cq), 155.9 (Cq), 154.5 (Cq), 143.5 (Cq), 143.2 (Cq), 142.2 (Cq), 132.5 (CH), 132.2 (Cq), 123.6 (Cq), 123.0 (CH), 121.3 (Cq), 119.6 (CH), 118.2 (CH), 26.2 (CH2), 21.9 (CH2) 21.8 (CH2), 21.5 (CH2), 17.7 (CH3); m/z (ES) (Found: MH+, 416.1492. C23H20F3NO3 requires MH, 416.1473).

Toxoplasma gondii

Parasite Strains (Isolates)
RH-YFP tachyzoites, (McPhillie et al, 2016; Fomovska et al, 2012; Gubbels et al, 2003), EGS strain (Vidigal et al 2015; Paredes-Santos et al 2012; McPhillie et al, 2016), Pru-luciferase, Me49, and RPS13A on the RH strain background (Hutson et al, 2010) were prepared and passaged in human foreskin fibroblasts [HFF] as described.

T.gondii in vitro

In Vitro Challenge Assay for T.gondii
RH strain YFP Tachyzoites
Protocol was adapted from Fomovska, et. al (2012; 2012a) for HFF. HFF were cultured on a flat, clear-bottomed, black 96-well plate to 90%-100% confluence. IMDM (1x, [+ ] glutamine, [+ ] 25 mM HEPES, [+ ] Phenol red, 10% FBS [Gibco, Denmark]) was removed and replaced with IMDM-C(1x, [+ ] glutamine, [+ ] 25 mM HEPES, [- ] Phenol red, 10% FBS)[Gibco, Denmark]). RH-YFP, lysed from host cells by passing twice through a 27-gauge needle, were counted and diluted to 32,000/mL in IMDM-C. HFF were infected with 3200 RH-YFP, then returned to 37°C, CO2 (5%) incubator for 1-2 hours for infection. Various concentrations of the compounds in 20 μL IMDM-C were added to each well. There were triplicates for each condition. Controls were pyrimethamine/sulfadiazine (standard treatment), 0.1% DMSO only, HFF only, and untreated cultures of HFF infected with 2 fold dilutions of YFP expressing parasites (called “YFP gradient” to establish amount of color from known numbers of YFP expressing parasites). Cells were incubated at 37°C for 72 hours. Plates were read using a fluorimeter (Synergy H4 Hybrid Reader, BioTek) to ascertain amount of relative fluorescence units (RFU) YFP, to measure parasite burden after treatment. Data were collected using Gen5 software with IC_{50} calculated by graphical analysis in Excel.
An initial screening assay of 10 µM, 1µM, 100 nM, and 10 nM of the compounds was performed. Compounds were not considered effective or pursued for further analysis if there was no inhibition of tachyzoites at 1µM. If compounds were effective at 1 µM, another experiment was performed to assess effect at 1 µM, 500 nM, 250 nM, 125 nM, 62.5 nM, and 31.25 nM.

**Cytotoxicity Assays in parallel with RH Strain *T.gondii* in vitro studies**

Toxicity assays used WST-1 cell proliferation reagent (Roche) as in Fomovska, et. al.(2012). HFF were grown on a flat, clear-bottomed, black 96-well plate. Confluent HFF were treated with inhibitory compounds at concentrations of 10 µM and 50 µM. Compounds were diluted in IMDM-C, and 20 µl were added to each designated well, with triplicates for each condition. A gradient with 2 fold-decreasing concentrations of DMSO from 10% to 0% in colorless, translucent IMDM-C was used as a control. The plate was incubated for 72 hours at 37° C. 10 µl WST-1 reagent (Roche) were added to each well. Cells were incubated for 30-60 minutes. Absorbance was read using a fluorimeter at 420 nm. A higher degree of color change (and absorbance) indicated mitochondrial activity and cell viability.

**In vitro Challenge Assay for EGS strain Bradyzoites**

HFF cells were grown in IMDM on removable, sterile glass cover slips in the bottom of a clear, flat-bottomed 24-well plate. Cultures were infected with 3x10⁴ EGS strain parasites per well, in 0.5 mL media. The plate was returned to incubator at 37° C overnight. The following day, the media was removed. Colorless IMDM and compounds were added to make various concentrations of the drug. Total volume was 0.5 mL. 2 wells had media only, as a control. Plates were returned to the 37° C incubator for 72 hours, checked once each 24 hours. If tachyzoites were visible in the control before 72 hours, cells were fixed and stained.

Cells were fixed using 4% paraformaldehyde and stained with Fluorescein-labeled Dolichos Biflorus Agglutinin, DAPI, and BAG1. Disks were removed, mounted on glass slides, and visualized using microscopy (Nikon Tl7). Slides were scanned using a CRi Panoramic Scan Whole Slide Scanner and viewed using Panoramic Viewer Software. Effects of compounds were quantitated by counting cysts in controls and treated cultures. Dolichos staining delimited structures and single organisms that remained were counted in a representative field of view. This was then multiplied by a factor determined by the total area of the cover slip in order to estimate the number of cysts and organisms in each condition. When the following forms were observed: “true cysts” with a dolichos-staining wall, “pseudocysts” or tight clusters of parasites, and small organisms, if there were fewer than four parasites visible in a cluster, organisms were counted individually (as “small organisms”). The entire scanned coverslip with all fields was also reviewed by 3 observers to confirm consistency.

**Synergy studies with RH strain YFP Tachyzoites**

Atovaquone and pyrimethamine were used to test whether they are synergistic with JAG21. Serial dilutions of the combination of JAG21 and either atovaquone or pyrimethamine were used in an in vitro challenge assay as described above. The EC50 of each compound and the combination of two compounds were determined. The effect of the combination of drugs was calculated with the following formula: \( C = \frac{[A]c}{[A]a} + \frac{[B]c}{[B]a} \). If C is lower than 1, the two compounds tested have
synergistic effect; if C is greater than 1, the two compounds tested have antagonist effect and if C is 1 they are additive.

**T.gondii** and HFF Mitochondrial Membrane Potential Measurements—The mitochondrial membrane potential was measured by the safranine method according to Vercesi et al. (1998). Freshly egressed *T. gondii* tachyzoites were filtered and washed twice with intracellular buffer (125 mM sucrose, 65 mM KCl, 10 mM HEPES-KOH buffer, pH 7.2, 1 mM MgCl₂ and 2.5 mM potassium phosphate). After washing, the parasites were resuspended in the same buffer at 10⁸/ml. An aliquot of 50 µl of this suspension was added to a cuvette containing Safranin O, 2.5 µM and Succinate 1 mM in final volume of 2 mL of the intracellular buffer. The fluorescence was measured with a Hitachi 7000 spectrofluorometer with setting Ex. 495/Em. 586. Once the baseline fluorescence is testable, 30 µM digitonin was added to permeabilize the parasites. 85 seconds after permeabilization, the THQ derivatives, dissolved in DMSO, were added. 5 µM of FCCP (Carbonyl cyanide-4-(trifluoromethoxy) phenylhydrazone) was used as an uncoupler reference for calculations and its effect was considered 100%. We used similar conditions for measuring the mitochondrial potential of mammalian cells with the following changes: The mammalian cells were resuspended at 10⁶/ml. We also used 50 µl of mammalian cells for each run in a cuvette with 2 µl solutions. The substrate used for mammalian cells was 5 mM glutamate and 5 mM malate. A higher concentration of digitonin (50 µM) was used to permeabilize the mammalian cells. The compounds were added at ~400 seconds after permeabilization. Each experiment was repeated at least three times in duplicates. Statistical analysis, unpaired student t test, was performed using GraphPad Prism 8.0 (GraphPad Software, Inc., San Diego, CA).

**Structure Activity Relationship (SAR) and comparison of effect on *T.gondii* and HFF enzyme activity.** The effects of changing R1 as 7-Et, 7-Me, 6-CF₃, or 6-Me on activity against RH strain tachyzoites, kinetic solubility, and metabolic stability were compared. Kinetic solubility and metabolic stability in human or murine liver microsomes were measured. The hERG (human Ether-à-go-go-Related) liability was also determined. The hERG gene (KCNH2) encodes a protein Kᵥ11.1, the alpha subunit of a potassium ion channel. This channel conducts the rapid component of the delayed rectifier potassium current, IKr, which is critical for repolarization of cardiac action potentials. A reduction in hERG currents from adverse drug effects can lead to long QT interval syndromes. These syndromes are characterized by action potential prolongation, lengthening of the QT interval on surface EKG, and an increased risk for "torsade de pointes" arrhythmias and sudden death. The MDCK-MDR1 Permeability Assay was also performed. MDCK-MDR1 refers to the ability of a compound to permeate across membranes of MDCK-MDR1 (Madin Darby canine kidney [MDCK] cells with the MDR1 gene [ABCB1], the gene encoding for the efflux protein, P-glycoprotein (*P-gp*)) *in vitro*. Assessing transport in both directions (apical to basolateral and basolateral to apical across the cell monolayers enables an efflux ratio to be determined. This provides an indication as to whether a compound undergoes active efflux (mediated by *P-gp*). This provides a prediction of blood brain barrier (BBB) penetration potential/permeability and efflux ratio. Effect in CACO-2 (Colon Adenocarcinoma cells) as a permeability assay and on cytochrome P450 CYP 450 were also determined. CYP enzymes catalyze oxidative biotransformation (phase 1 metabolism) of most drugs CYP enzymes, bind to membranes in a cell (cyto) and contain a heme pigment (chrome and P) that absorbs light at a wavelength of 450 nm when exposed to carbon monoxide. Metabolism of a drug by
CYP enzymes is a major source of variability in drug effect. These were measured by Chem Partners. The relative effect on HFF and parasite enzymes also were compared.

**RPS13Δ Tachyzoites in Human Primary Brain Neuronal Stem Cells in vitro for transcriptomics and transcriptomics analyses**

Culture of Human Primary Brain Neuronal Stem Cells (NSC) was as described (McPhillie et al, 2016; Ngo et al, 2017); *T. gondii* RPS13Δ on RH strain background (Hutson et al, 2010) was used to infect the NSC as described (McPhillie et al, 2016; Ngo et al, 2017). RNA was isolated and prepared and used for transcriptomic experiments as dervibed (McPhillie et al, 2016; Ngo et al, 2017). Briefly, NSC, initially isolated from a temporal lobe biopsy (Walton et a, 2006) were infected with either wild-type or RPS13Δ RH tachyzoites using biological duplicates at a multiplicity of infection of 2:1 and incubated as previously described (Ngo et al, 2017). Eighteen hours post-infection, extracellular parasites were washed out with cold PBS before total RNA extraction. Further isolation of the mRNA fraction was carried out with miRNeasy Mini Kit columns (Qiagen) following manufacturer instructions and Illumina barcoded mRNA sequencing libraries were constructed with TruSeq RNA Sample Preparation Kits v2 (Illumina). Libraries were sequenced as 100 bp single reads with Illumina HiSeq 2000 apparatus at a sequencing depth of ~3 Gbp per sample. Sequencing reads were mapped to the human (release GRCh38) and *T. gondii* ME49 strain (ToxoDB release 13.0) reference genome assemblies with hisat2 (Kim et al, 2015) and raw read counts were per gene were estimated with HTSeq (Anders et al, 2015). Identification of parasite genes that were differentially expressed between wild-type and RPS13Δ parasites was performed with the R package DESeq2 (Love et al, 2014) using a generalized linear model likelihood ratio test. Identification of orthologous genes between *T. gondii* and *P. cynomolgi* was carried out by best-reciprocal matches between *T. gondii* and *P. cynomolgi* proteomes using Blastp and a e-value cutoff of 1 x 10^-3. The list of Genes that are differentially expressed between *P. cynomolgi* hypnozoites and the liver-schizont stage was extracted from a previously published study by Cubi R. et al (Cubi et al, 2017). Gene set enrichment analysis was carried out with the GSEA tool (Subramanian et al, 2005) using *T. gondii* Gene Ontology and cell cycle gene sets developed by Croken M et al (Croken et al, 2014) and visualized with the Enrichment Map application in Cytoscape (Su et al, 2014).

**T.gondii in vivo**

Type II parasites in vivo

IVIS. Balb/C mice were infected intraperitoneally (IP) with 20x10^3 *T. gondii* (Prugneaud strain expressing luciferase) tachyzoites. Treatment began 2 hours later with JAG21 (5mg/kg) which was dissolved in DMSO, administered IP in a total volume of 0.05ml. Mice were imaged every second day starting on day 4 post infection using an IVIS Spectrum (Caliper Life Sciences) for minute exposures, with medium binning, 20 minutes post injection with 150 mg/kg of D-luciferin potassium salt solution.

Brain cysts:
Brain cysts were searched for in paraffin imbedded tissue of the surviving Prugneaud strain infected treated Balb/C mice in the IVIS study, 30 days after infection which was 16 days after treatment had been discontinued. All treated mice had survived. There were no surviving untreated mice in those experiments.

In separate experiments, Balb/C mice were infected IP with 20 x 10^3 T. gondii Me49 strain tachyzoites. In these separate studies of mice with established chronic infection, after 30 days, IP treatment with JAG21 was begun each day for 14 days. JAG21 was dissolved in DMSO and administered IP in a total volume of 0.05ml. In experiments when tafenoquine was administered alone or with JAG21 in some groups 3mg/kg tafenoquine was administered once on day -1 from when JAG21 treatment was initiated. Cysts in brain were quantitated on day 30, 16 days after discontinuing JAG21. Immunoperoxidase staining was performed. Parasite burden was quantitated in two ways. The first was using a positive pixel count algorithm of Aperio ImageScope software. Positive pixels were normalized to tissue area (mm^2). Briefly, automated quantitation was done by counting positive pixels per square area. The entire brain in one section was scanned for each mouse. The Cyst burden was quantitated as units of positive pixels per mm^2. The average +/- S.E.M. numbers of mm^2 per slide quantitated was 30.2 +/- 1.6 square mm per mouse for this quantification. Each highpower field of view shown in Fig. 5C is approximately 0.02 mm^2 per field of view. Cysts on each slide for each condition in two biological replicate experiments were also quantitated by 2 separate observers independently and results compared with automated counting, separately.

RPS13 Δ in vivo

This G1 arrested parasite persists in tissue culture for prolonged times in the absence of tetracycline (Hutson et al 2010), but in immune competent mice it cannot be rescued with tetracycline, or LNAME (L-N^G^-Nitro arginine methyl ester, an analog of arginine) used as an antagonist of nitric oxide synthase (NOS) that inhibits NO production, or both together (Hutson et al 2010).

In pilot studies, herein, interferon γ receptor knockout mice that were not treated were observed following infection. At 7 and at 14 days following infection, spleen and liver were removed and immune peroxidase stained. At 14 days a group of mice were treated with anhydro tetracycline and when a subset of these mice died their spleen and liver were removed and immune peroxidase stained.

As in the pilot studies, this RPS13 Δ parasite also was used to infect interferon γ receptor knockout mice in a treatment study. The design of this experiment with these immune compromised mice is shown in Fig. 6. In this separate study, groups of mice were infected with RPS13 Δ. They were treated with tafenoquine on day -1, or JAG21 for 14 days 2 hours after infection, or the two together with tafenoquine on day -1 and JAG21 for the first 14 days, or with diluent only for 14 days, as described above. For the initial 14 days no tetracycline was administered. After that time tetracycline was administered. Mice were observed each day. At the time they appeared to have substantial illness or at the termination of the experiment they were euthanized, tissues fixed in formalin and stained with hematoxylin and eosin or immunoperoxidase stained and parasite burden was assessed.
**RH challenge in a study of oral administration of a novel nano formulation of JAG21:**

**Nanoformulation of JAG21 for oral administration in *T. gondii* studies.** JAG21 was prepared using hydroxyethyl cellulose (HEC) and Tween 80. Briefly, this dispersant solution containing 5mg/mL HEC and 2mg/mL Tween 80 in water was prepared. Solid JAG21 was added to 20mg/mL, and the dispersion was sonicated for 60 seconds using a Sonics v50 probe-tip sonicator set to 20kHz to homogenize. Sonication was performed at room temperature. Aliquots of the homogeneous dispersion were frozen and lyophilized using a VirTis AdVantage freeze dryer. These aliquots were stored at room temperature for 5-6 months. Prior to dosing, aliquots were reconstituted using water. Controls containing no JAG21 were also prepared. Following reconstitution with water, the dispersion was imaged using a Nikon ECLIPSE E200 optical microscope set to 40x magnification. The average particle size of the JAG21 dispersion in HEC/Tween 80 was determined using an in-house image analysis program. This novel method to stably formulate JAG21 was discovered after all other studies were completed and this was the last experiment in this manuscript performed as a consequence.

**RH YFP challenge.** For studies of the nano formulated JAG21, this was administered for one or three days by gavage in the doses shown in the results section. These C57BL6 background mice received 2000 RH tachyzoites IP. on day the first day of the experiment and peritoneal fluid was collected 5 days later to quantitate fluorescence and numbers of parasites.

**Malaria assays**

**Enzyme assays:**

Methods for enzyme assays:

**Materials**

*P. falciparum* 3D7 strain were obtained from the Liverpool School of Tropical Medicine. Protease cocktail inhibitor was obtained from Roche. Bradford protein assay dye reagent was obtained from Bio-Rad. All other reagents were obtained from Sigma-Aldrich. Decylubiquinol was produced as per Fisher *et al.* (2009). In brief, 25 mg of decylubiquinone were dissolved in 400 μl of nitrogen-saturated hexane. An equal volume of aqueous 1 M sodium dithionite was added, and the mixture vortexed until colorless. The organic phase containing the decylubiquinol was collected, the solvent was evaporated under N2 and the decylubiquinol finally dissolved in 100 μl of 96% ethanol (acidified with 10 mM HCl). Concentrations of decylubiquinol was determined spectrophotometrically on a Cary 300 Bio UV/visible spectrophotometer (Varian, UK) from absolute spectra, using ε288 - 320 = 8.1 mM-1 cm-1. Decylubiquinol was stored at -80 °C and used within two weeks.

*P. falciparum* culture and extract preparation

*P. falciparum* strain 3D7 blood-stage cultures were maintained by the method of Trager and Jensen (1976). Cultures contained a 2% suspension of O+ human erythrocytes in RPMI 1640 medium containing L-glutamine and sodium carbonate, and supplemented with 10% pooled human AB+ serum, 25 mM HEPES (pH 7.4) and 20 μM gentamicin sulphate. Cultures were grown under a gaseous headspace of 4 % O2 and 3% CO2 in N2 at 37°C. Cultures were grown to a parasitemia of 5 % before use.
The protocol for the preparation of parasite extract was adapted from Fisher et al.\textsuperscript{30}. Free parasites were prepared from infected erythrocytes pooled from five T75 flasks, by adding 5 volumes of 0.15\% (w/v) saponin in phosphate-buffered saline (137 mM NaCl, 2.7 mM KCl, 1.76 mM K\textsubscript{2}HPO\textsubscript{4}, 8.0 mM Na\textsubscript{2}HPO\textsubscript{4}, 5.5 mM D-glucose, pH 7.4) for 5 min, followed by three washes by centrifugation in RPMI containing HEPES (25 mM), and a final resuspension in potassium phosphate buffer (50 mM K\textsubscript{2}HPO\textsubscript{4}, 50 mM KH\textsubscript{2}PO\textsubscript{4}, 2 mM EDTA, pH7.4) containing a protease inhibitor cocktail (Complete Mini; Roche). Parasite extract was then prepared by disruption with a sonicating probe for 5 s, followed by a 1 min rest period on ice to prevent the sample overheating. This process was performed three times. The parasite extract was used immediately. The protein concentration of the parasite extract was determined by Bradford protein assay (Bio-Rad).

\textbf{Pfbc\textsubscript{1} native assay}

\textit{P. falciparum} bc\textsubscript{1} complex cytochrome c reductase (Pfbc\textsubscript{1}) activity was measured by monitoring cytochrome c reduction at 550 versus 542 nm using a Cary 300 Bio UV-Visible Spectrophotometer (Varian, UK), using a protocol adapted from Fisher et al. (2009). The assay was performed in potassium phosphate buffer in a quartz cuvette and in a final volume of 700 µL. Potassium cyanide (10 µM), oxidized cytochrome c (30 µM), parasite extract (100 µg protein) and compound/DMSO were added sequentially to the cuvette, with mixing between each addition. Test compounds were added to a final concentration of 1 µM. DMSO (0.1\% v/v) and atovaquone (1 µM), a known malarial cytochrome bc\textsubscript{1} complex inhibitor, were used as negative and positive controls respectively. The reaction was initiated by the addition of 50 µM decylubiquinol and allowed to proceed for 3 min.

\textbf{Malaria parasite In vitro studies:}

Malaria potency testing in vitro was performed using 4 different \textit{P. falciparum} strains, D6, TM91-C235, W2, and C2B. The D6 strain is a drug sensitive strain from Sierra Leone, the TM91-C235 strain is a multi-drug resistant strain from Thailand, the W2 strain is a chloroquine resistant strain from Thailand, and the C2B strain is a multi-drug resistant strain with resistance against atovaquone. These assays were performed as described below.

\textbf{Compound Activity against \textit{Plasmodium falciparum}}

Compound activity against \textit{P. falciparum}, was tested using the Malaria SYBR Green I - Based Fluorescence (MSF) Assay. The complete method for performing this microtiter assay is described in previous work published by Plouffe \textit{et al.}(2008) and Johnson \textit{et al.}(2007). In brief, this assay uses the binding of the fluorescent dye SYBR Green I to malaria DNA to measure parasite growth in the presence of two-fold diluted experimental or control. The relative fluorescence of the intercalated SYBR Green I proportional to parasite growth, and inhibitory compounds will result in lower observed fluorescence compared to untreated parasites.

\textbf{Cytotoxicity assays in parallel with \textit{P.falciparum} assays in vitro}

Toxicity studies also were performed with HepG2 cells (human liver cancer immortal cell line derived from the liver tissue of a 15-year-old African American, ATCC \textsuperscript{R} HB-8065\textsuperscript{TM}) in parallel with the studies of \textit{P.falciparum}, with inhibitors in vitro, as described in McPhillie \textit{et al.}(2016).
P. berghei causal prophylaxis in vivo model

P. berghei sporozoites were obtained from laboratory-reared female Anopheles stephensi mosquitoes which were maintained at 18 degrees C for 17-22 days after feeding on a luciferase expressing P. berghei infected Swiss CD1ICR. Using a dissecting microscope, the salivary glands were extracted from malaria-infected mosquitoes and sporozoites were obtained. Briefly, mosquitoes were separated into head/thorax and abdomen. Thoraxes and heads were triturated with a mortar and pestle and suspended in medium RPMI 1640 containing 1% C57BL/6 mouse serum (Rockland Co, Gilbertsville, PA, USA). 50–80 heads with salivary glands were placed into a 0.5 ml Osaki tube on top of glass wool with enough dissection media to cover the heads. Until all mosquitoes had been dissected, the Osaki tube was kept on ice. Sporozoites that were isolated from the same batch of mosquitoes were inoculated into C57BL/6, 2D knock-out and 2D knock-out/2D6 knock-in C57BL/6 mice on the same day to control for biological variability in sporozoite preparations. On day 0, each mouse was inoculated intravenously in the tail vein with approximately 10,000 sporozoites suspended in 0.1 ml volume. They were stained with a vital dye containing fluorescein diacetate (50 mg/ml in acetone) and ethidium bromide (20 µg/ml in phosphate buffered saline; Sigma Chemical Co, St. Louis, MO, USA) and counted in a hemocytometer to ensure that inoculated sporozoites were viable following the isolation procedure. Viability of the sporozoites ranged from 90 to 100%.

Animals

The mice used in these experiments were albino C57BL/6 female mice which were housed in accordance with the current Guide for the Care and Use of Laboratory Animals (1996) under an IACUC approved protocol. All animals were quarantined for 7 days upon arrival, and the animals were fed standard rodent maintenance food throughout the study.

Test compounds, homogenization of JAG21 creating a nanoformulation, and administration

Animals were dosed with experimental compounds based on body weight. The suspension solution of orally administered drugs were conducted in 0.5% (w/v) hydroxyethyl cellulose and 0.2% Tween 80 in distilled water. To insure the size of the compounds in the dosing solution were under 50 µM (measured they were 4-6 µ), the suspension was homogenized using a homogenizer (PRO Scientific Inc, Monroe, CT, USA) with a 10 mm open-slotted generator running at 20,000-22,000 rpm for 5 min in an ice bath. The compounds were made fresh each day and used immediately (always in <1/2 hour). Stability beyond that time was not determined. It was not anticipated that they would be stable beyond that time.

Compounds were administered on 3 consecutive days (−1, 0, +1) relative to sporozoite infection or a single dose on day 0. Drug suspensions were administered to mice by oral gavage using an 18 gauge intragastric feeder. For the 3 day dosing regimen, compounds were administered at 0.625 mg/kg and for the single dose regimen administered on day 0, compounds were administered at 2.5 mg/kg.

In vivo imaging

All of the in vivo bioluminescent imaging methods utilized have been described previously. Briefly, JAG21 was administered orally on days −1, 0 and 1 with respect to sporozoite inoculation. All inoculated mice were imaged using the Xenogen IVIS-200 Spectrum (Caliper Life Sciences, Hopkinton, MA, USA) IVIS instrument at 24, 48 and 72 hours post-sporozoite infection. The
bioluminescent imaging experiments were conducted by IP injection of the luciferase substrate, D-Luciferin potassium salt, (Xenogen, California and Goldbio, St Louis, MO, USA), into mice at a concentration of 200 mg/kg 15 min before bioluminescent images were obtained. Three minutes after luciferin administration the mice were anesthetized using isoflurane, and the mice were positioned ventral side up on a 37 degrees C platform with continual anesthesia provided through nose cone delivery of isoflurane. All bioluminescent images were obtained using 5minute exposures with f-stop = 1 and large binning setting. Photon emission from specific regions was quantified using Living Image® 3.0 software (Perkin Elmer),

Additionally, blood stage parasitemia was assessed 3 days after imaging was completed by treating small quantities of blood obtained from tail bleeds with the fluorescent dye Yoyo-1 measured by using a flow cytometry system (FC500 MPL, Beckman Coulter, Miami, FL, USA), (Pybus et al, 2013; Marcissin et al, 2014)

Methods for Co-Crystallization and binding studies

Bovine cytochrome bc₁ activity assays.

Bovine cytochrome bc₁ inhibition assay was carried out in 50mM KPi pH 7.5, 2 mM EDTA, 10mM KCN, 30µM equine heart cytochrome c (Sigma Aldrich), and 2.5 nM bovine cytochrome bc₁ at room temperature. 20 mM inhibitors dissolved in DMSO were added to the assay at a desired concentration without prior incubation. The working concentration of DMSO in the assay did not exceed 0.3% v/v. The reaction was initiated by the addition of 50 µM decylubiquinol (Abcam). The reduced cytochrome c was monitored by the different absorption between 550 and 542 nm using extinction coefficient of 18.1 mM⁻¹cm⁻¹ in a SPECTRAmax Plus 384 UV-visible Spectrometer. The initial kinetic rate is determined as a zero-order reaction and used as the specific activity of cytochrome bc₁.

Bovine Cytochrome bc₁ purification protocol:

Preparation of crude mitochondria

Whole fresh bovine heart was collected after slaughter and transported in ice. All work was carried out at 4 °C. Lean heart muscle was cut into small cubes and homogenized in the buffer composed from 250 mM sucrose; 20 mM K₂HPO₄; 2 mM succinic acid; 0.5 mM EDTA. Buffer was added at a ratio of 2.5L per 1 kg of muscle tissue. Ph of resulting homogenate was adjusted to 7.8 using 2 M Tris and PMSF protease inhibitor was added to 0.1 mM concentration. The homogenate was then centrifuged in a Sorvall GS-3 rotor at 5000g for 20 mins. The resulting supernatant was then transferred to a Sorvall GSA rotor and centrifuged at 20,000g for 20 mins. Obtained mitochondrial pellet was washed in 50 mM KPi (pH 7.5); 0.1 mM PMSF buffer before second centrifugation under the same condition. The pellet was collected and stored at -80 °C for further use.

Solubilisation of membrane proteins

The frozen mitochondria were thawed and re-suspended in 50 mM KPi (pH 7.5); 250 mM NaCl; 0.5mM EDTA; 0.1 mM PMSF buffer; a small sample was taken for quantification of total mitochondrial proteins by BCA assay. The remaining sample was centrifuged at 180,000g in
Beckman Ti70 rotor for 60 mins. The pellet was re-suspended in the same wash buffer with the addition 1 mg DDM per 1 mg of protein and then centrifuged under the same conditions for 60 mins. The pellet was discarded and the supernatant was collected for ion exchange chromatography.

Purification of cytochrome bc1

During purification the presence of protein was detected using 280 nm absorbance and the presence of heme was detected using 415 nm Soret band peak and 562 nm absorbance. The solubilized protein solution was applied on DEAE-Sepharose CL-6B column (ca. 50 ml, GE Healthcare) pre-equilibrated with buffer A (50 mM KPi (pH 7.5); 250 mM NaCl; 0.01 % w/v DDM; 0.5mM EDTA) and washed with 3 CV of buffer A. The protein was eluted by linear gradient with buffer B (50 mM KPi (pH 7.5); 500 mM NaCl; 0.01%w/v DDM; 0.5mM EDTA). Fractions containing cytochrome bc1 were pooled and concentrated to 0.5 ml using an Amicon Ultra-15 (Amicon, MWCO 100,000) concentrator. Concentrated sample was applied to a Sephacryl-S300 gel filtration column (ca. 120 ml) pre-equilibrated in buffer C (20 mM KMOPS (pH 7.2); 100 mM NaCl; 0.01%w/v DDM; 0.5 mM EDTA) and eluted at a flow rate of 0.5 ml/min. Purified cytochrome bc1 fractions were collected and concentrated to 40 mg/ml. PEG fractionation with increasing concentration of PEG4000 was used to precipitate cytochrome bc1. Precipitating solution (100 mM KMES pH 6.4; 10% PEG4000; 0.5 mM EDTA) was mixed with the protein to a desired PEG concentration. The precipitated protein pellet was re-solubilised in buffer D (25 mM KPi pH 7.5, 100 mM NaCl, 0.5 mM EDTA, 0.015% DDM) and dialysed in the same buffer in a centrifugal ultrafilter to remove residual PEG. 5 µM cytochrome bc1 was incubated at 4 °C for 12 hours with 50 µM JAC021 (10-fold molar excess) diluted from 20mM solution stock in DMSO.

Crystallization, data collection and refinement of Cytochrome bc1 - JAG021 complex

The inhibitor-bound cytochrome bc1 was mixed with 1.6% HECAMEG to the final protein concentration of 40 mg/mL. Hanging drop methods was used for crystallisation. 2 µL of final protein solution with 2 µL of reservoir solution (50 mM KPi pH 6.8, 100 mM NaCl, 3 mM NaN3, 10-12% PEG4000) was equilibrated over reservoir solution at 4 °C. The crystals were grown to 100 µm within four days. The single crystal was transferred in reservoir solution containing increasing to 50% concentrations of ethylene glycol prior to cryo-cooling in liquid nitrogen. X-ray data were collected from single crystal PROXIMA2 beamline, SOLEIL light source, France using DECTRIS EIGER X 9M detector at 0.9801Å wavelength up to 3.45Å resolution. Data were indexed and integrated using iMosflm (Battye et al, 2011), and scaled using Aimless (Evans, 2011). The starting model for refinement was 5OKD. All ligands except co-factors were removed from the model prior to refinement. Jelly-body refinement was carried out with Refmac5 (Murshudov et al, 2011). The inhibitor model was generated by Jligand (Lebedev et al, 2012). The model was manually edited in COOT (between cycle refinements. Data collection and refinement statistics are shown in Supplemental Table S1).

Co-cryo electron microscopy

Electron microscopy and image processing
Cryo-EM was carried out as described in Amporndanai et al. (2018). Briefly, 3 µL of sample at 5 mg/mL concentration were applied to Quantifoil Cu R1.2/1.3, 300 mesh holey carbon grids and plunge frozen using an FEI Vitribot (blot time 6 seconds, blot force 6). Data were collected on a FEI Titan Krios with a Falcon III direct electron detector operated in integrating mode at 300 kV. Automated data collection was carried out using EPU software with a defocus range of -1 to -3.5 µm, and a magnification of 75,000 x which yielded a pixel size of 1.065 Å. Data were collected for 72 hours resulting in 5,356 micrographs. The total dose was 66.4 e/Å over a 1.5 second exposure which was split into 59 frames. All of the processing was performed in RELION 2.1 unless otherwise stated. The initial drift and CTF correction was carried out using MOTIONCORR2 (Zheng et al., 2017) and Gctf (Zhang et al., 2016) respectively. The micrographs were examined and those with crystalline ice were initially removed resulting in 2,960 micrographs. A subset of ~2,000 particles were manually picked to generate 2D references to facilitate auto-picking resulting in 439,009 particles. These particles underwent an initial round of 2D classification with those classes that displayed clear secondary structure detail being taken forward to 3D classification and split into three classes. Two of the three classes generated a high-quality cytochrome bc1 reconstruction with secondary structure information clearly visible. The particles from these two classes were recombined to form the final datasets consisting of 211,916 particles in the final reconstruction. The particles were 3D refined using C2 symmetry to produce a map with resolution 3.8 Å. The particles also underwent movie refinement and particle polishing which further improved the resolution of the map to 3.7 Å. A previously refined EM structure for SCR0911 (pdb 6FO6) was fit into the map using UCSF chimera and subsequently refined using phenix with the correct ligand. The maps were then inspected manually in COOT (Emsley et al., 2004) and the model corrected for any errors in refinement and the placement of residues.

Statistical Analysis
A Pearson test was used to confirm a correlation between increasing dose and increasing inhibition. An ANOVA and subsequent pairwise comparison with Dunnett correction was used to determine whether or not inhibition or toxicity at a given concentration was statistically significant. Stata/SE 12.1 was used for this analysis.

RESULTS
THQ compounds are potent in vitro
Initially, a small library of seven compounds (Figs. 1 [blue and green font, Fig. 1A] and 2) were tested, and each compound was tested at least twice against T. gondii tachyzoites. JAG021 and JAG050 demonstrated effect below 1 µM, and were tested at lower concentrations. JAG050 and JAG021 were identified as lead compounds given the IC50 values obtained were 33 and 55 nM, respectively. Correlation between concentration of compound and inhibition of parasite replication (as measured by fluorescence) was observed for all compounds except JAG046. The relative effect on HFF and parasite enzymes were also compared, with those marked ** in Fig. 1A having the most effect on the parasite enzyme activity relative to host HFF enzyme activity as shown below in Fig 3.
A representative graph of these in vitro data is shown in Fig. 2A. Subsequently, a larger library of 54 compounds was synthesized to ascertain structure-activity relationships (SAR) (Fig. 1B). Our primary aims were to block putative metabolism of the terminal phenol ring of MJM170 and improve the solubility across the compound series. Substituents were generally tolerated at the meta and para positions on the phenol ring (R1), similar to the trends observed in the ELQ series (McPhillie et al, 2016; Dogget et al 2012, Vidigal et al 2002). The incorporation of heteroatoms into the aryl rings of the biphenyl moiety did not lead to improvements in solubility and biological activity. Small substituents were tolerated at the 7-position of the THQ bicyclic ring (Fig. 1B; R1), improving selectivity (see below, SAR) but not at the 6-position unlike the ELQ series. In summary, overall, nitrogen atoms not tolerated in aryl ring (C) and the 4-position was optimal for phenol substituent. Ultimately, no other compound had all the advantages of JAG21, although some of these were identified as potential back up compounds (marked with **), with greater selectivity for the parasite relative to the mammalian enzyme activity. Compound JAG21 displayed synergy against RH strain tachyzoites with atovaquone (Fig. 2C) but not with pyrimethamine, although no antagonism was observed (data not shown).

Cytotoxicity assays performed in parallel using HFF, WST-1 (Fomovska et al, 2012; Fomovska, et al 2012a), and HEP G2 cells demonstrated a lack of toxicity at concentrations substantially in excess of the concentrations effective against tachyzoites. Because T. gondii grows inside cells, if a compound were toxic to host HFF then it would make the compound appear to be spuriously effective (Fomovska et al, 2012; Fomovska, et al 2012a), when in actuality only toxicity for the host cell would be measured. Cytotoxicity to HFF was therefore assessed for all compounds at 10 μM. Results of this experiment are in Fig. 1A, toxicity column. A two-way ANOVA and subsequent pairwise comparison found none of the differences in absorbance, compared to the media-DMSO vehicle controls, to be statistically significant (p>0.05). Most of these compounds are not toxic at 10μM (the limit of solubility) and that cytotoxicity to cells can be attributed to DMSO in the solution, not the compound. Dose response testing (IC50) was performed with HEP G2 cells as described and the observed toxicity was: HEP G2 IC50 17.70 μM (r2= 0.97) for JAG021; 7.1 μM (r2=.98) for JAG050.

Lead compounds JAG050, JAG021 and others were tested against EGS strain (McPhillie et al, 2016; Vidigal et al, 2015; Paredes-Santos et al 2013; Paredes-Santos et al,2018) tachyzoites and encysted bradyzoites using methods described earlier (McPhillie et al, 2016). We found a number of these compounds including JAG21 were highly effective against tachyzoites (RH-YFP; Fomovska et al, 2012) (Figs. 1A, 2A,C) and bradyzoites of EGS (McPhillie et al, 2016; Vidigal et al, 2015; Paredes-Santos et al 2013; Paredes-Santos et al,2018) (Fig 2B). For example, in a separate experiment (data not shown) using immunofluorescence microscopy, the following forms were observed: “true cysts” with a dolichos-staining wall, “pseudocysts” or tight clusters of parasites, and small organisms. If there were fewer than four parasites visible in a cluster, organisms were counted individually (as “small organisms”). A statistically significant reduction in the number of true cysts and small organisms was observed at 1 μM and 10 μM for both compounds (p <0.05, p<0.005). 500nM JAG21 treatment results in cultures where we do not see EGS bradyzoites (e.g., Fig. 2B).

Results against P. falciparum using methodology described earlier (McPhillie et al, 2016,Trager et al, 2005, Ploué et al,2008, Johnson et al, 2007 ) also are shown in Fig. 2D. JAG 21 is potent
against *P. falciparum* with IC50 values ranging from 14-61 nM against a variety of drug sensitive
and resistant strains ([McPhillie et al 2016](#)) including D6, TM91-C235, W2, and C2B. The D6
strain is a drug sensitive strain from Sierra Leone, the TM91-C235 strain is a multi-drug resistant
strain from Thailand, the W2 strain is a chloroquine resistant strain from Thailand, and the C2B
strain is a multi-drug resistant strain resistant to atovaquone. Effects of other comparison
compounds are also shown in this table and range from 31 to 20,000 nM (**Fig. 2D**).

**ADMET superiority of JAG21**

*In vitro* absorption, distribution, metabolism, excretion, and toxicity (ADMET) analyses of the
THQ compounds were outsourced to ChemPartner Shanghai Ltd. ELQ-271 (synthesized in-house)
was tested as a comparison. THQs which were potent inhibitors of *T. gondii* tachyzoites were
assessed for their kinetic solubility, metabolic stability in human and mouse liver microsomes (**Fig.
2E**), hERG, and their ability to permeate across MDCK-MDR1 cell membranes (*in vitro* measure
of blood-brain barrier (BBB) penetration potential/permeability). Solubility, half-life, HERG, and
BBB permeability/efflux results are shown in **Fig. 2F**. The aqueous solubility (PBS, pH 7.4) of
amorphous compounds JAG021 and JAG050 was 7 and 16 µM respectively, which is improved
over MJM170 (2 µM) and ELQ-271 (0.2 µM). We also tested solubility of the microcrystalline
form of JAG21 and found that the solubility was 3.5 µM. JAG021 was the most metabolically
stable compound in human liver microsomes (>99% remaining after 45 mins) compared with other
THQs and ELQ-271, although it displayed a much shorter half-life of 101 mins in mouse liver
microsomes. All THQs tested in the MDCK-MDR1 system for blood brain barrier (BBB)
permeability (including MJM170, JAG021 and JAG050), exhibited high permeability (P_{app} >10 x
10⁶ cm/s) and low efflux (efflux ratio <1.5).

**THQs potently inhibit parasite Cytochrome bc1 (Cytbc1) enzyme activity**

JAG21 is the most active of the initially tested THQs against *T. gondii* Cytbc1, which also showed
selectivity for the parasite over the mammalian mitochondrial membrane potential (**Fig. 3**).
Following the full SAR testing *in vitro* activity against tachyzoites, the full set of compounds was
tested against HFF; then the initial compounds also were tested against the *T.gondii* and HFF
enzyme benchmarked against atovaquone, and ultimately the full set of compounds was compared
for effect against the *T. gondii* and HFF enzymes.

Mitochondrial membrane potential measurements were performed with permeabilized *T.gondii*
tachyzoites in suspension using safranin O, which loads into polarized membranes (see Materials
and Methods in the supplemental materials [Vercesi,1998]). *T. gondii* tachyzoites were
permeabilized with digitonin to allow the mitochondrial substrate succinate to cross the membrane
and energize the mitochondrion. The fluorescence of safranin O, which loads into energized
mitochondria was used to measure the membrane potential. The energized state of the
mitochondrion is observed by a decrease in fluorescence (**Figs. 3A, C, E**). Trifluoromethoxy
carbonylcyanide phenylhydrazone (FCCP) was used to depolarize the membrane, which causes
the fluorescence to go up as shown in **Fig. 3A**. JAG21 depolarized the membrane potential even
at concentrations as low as 2 nM (**Fig. 3C, D**). JAG21 and Atovaquone had similar effects on the
mitochondrial membrane potential (**Fig. 3D**). **Fig. 3F** is host cells so indicates that it is less toxic.
Other compounds like JAG46 and 47 showed almost no effect at doses as high as 4 µM (**Fig.
3A,B**). JAG50 showed depolarizing activity at doses of 200 nM and higher. The effect of these
THQ compounds against the *T. gondii* mitochondrial membrane potential was greater than the
effect on the human foreskin fibroblast membrane potential (**Fig. 3E,F**). This is consistent with
the observation that JAG21 is less toxic against human Telomerase reverse transcriptase
Enzyme reduction of cytochrome \( c \) by \( P. \) falciparum parasite extract (Fisher et al, 2004, 2009) is mediated by \( P. \) falciparum \( bc_{1} \) complex cytochrome \( c \) reductase (\( Pfbc_{1} \)) enzyme. All three compounds tested (1 \( \mu \)M) significantly inhibited the reduction of cytochrome \( c \) by the \( P. \) falciparum parasite extract, (JAG021 = 86.4 ± 3.2; JAG099 = 81.3 ± 6.0; MJM170 = 69.7 ±11.3 % of the atovaquone response, Fig. 3G. Additional data demonstrated selective effect on \( P. \) falciparum enzyme compared with bovine enzyme (data not shown).

**Binding, Co-crystallography, Pharmacophore and Co-Cryo-Electron Microscopy Studies Demonstrate Selectivity**

In binding assays and in co-crystallography (McPhillie et al, 2016; Capper et al, 2015; Amporndanai et al, 2018; Battye et al, 2011; Emsley et al, 2010; Laskowski and Swindells, 2011; Lbebedev et al, 2012; Murshudov et al, 2011; Emsley et al, 2004; Zheng et al, 2017; Zhang et al, 2016), JAG021 has lower binding affinity to bovine cytochrome \( bc \) in comparison with previous compounds that we have tested. JAG 21 ‘inhibits' \( Cytc1 \) but not fully, indicating that it will be less toxic for mammalian (bovine/human) \( cyt \) \( bc \) than the apicomplexan enzymes (Fig. 4A). The electron density map in the Qi site of bovine cytochrome \( bc_{1} \) complex with JAG021 (Table S1, Data Collection Statistics) reveals an additional electron density, which allowed unambiguous positioning of the inhibitor (Fig. 4B). No additional electron density was found within the Qo site. After the refinement, 2Fo-Fc electron around JAG021 becomes clearer (Fig. 4C). The second aromatic ring in the tail group of the compound is less defined due to high flexibility introduced by the oxygen linker. The quinolone head of JAG021 is held between Asp228 and His201 and adapted the same conformation as 4(1H)-pyridone (GSK9321211(Capper et al, 2015) (Fig. 4D) and tetrahydro-4(1H)-quinolone (MJM170) (McPhillie et al, 2016) (Fig. 4E) by directing the NH group to His201 and the carbonyl group to Asp228. The carbonyl of the quinolone head and OG1 atom of Ser35 are within 3.0 Å distance that allows hydrogen bonding and enhances the binding affinity to the bovine enzyme. The 3-diarylether tail extends along a hydrophobic channel defined by Gly38, Ile39 and Ile42. The trifluoromethoxy group at the phenoxy ring points towards Met190 and Met194 (Fig. 4F). CryoEM studies of the complex also demonstrates reasons for selectivity. In Fig. 4F, the density suggests that the inhibitor can adopt two different binding poses as observed previously in the cryo-EM structure of GSK932121(Capper et al, 2015). The binding pose shown in yellow, which has the strongest density, agrees with the crystal structure and has the trifluoromethoxy group pointing towards Met194. However, there is additional density which could result from a second binding pose (green) in which the trifluoromethoxy group points towards Asp228(McPhillie, 2016 et al). Fig. 4F, shows GSK932121 pyridone (PDB:4D6U) (G) MJM170 quinolone (PDB:5NMI).

**JAG21 is potent *in vivo***

*In vivo* studies of JAG21 against *T. gondii* demonstrated high efficacy in a variety of settings. JAG21 at 5 mg/kg/day administered IP improves well-being and eliminates illness and *T. gondii* Type II Prugneaud luciferase tachyzoites completely in luminescence studies (Fig. 5A). Further,
treatment beginning on day one after infection results in no cysts being found in brains of these mice treated for 14 days with 5mg/kg/day of JAG21, when brains were evaluated 30 days after stopping JAG21 treatment in two replicate experiments. Treatment beginning on day 30 after initiation of infection with Type II Me49 parasites results in marked, statistically significant reduction in normal appearing cysts, free organisms and immunoperoxidase stained cysts detected by automated imaging of scanned slides (Figs. 5 B,C, p<0.03 experiment; p<0.01 experiments 1 and 2 together, Supplemental Fig. S1). The automated analysis confirmed results from the blinded microscopic visual quantitation of cysts and free organisms in slides by two observers. Adding tafenoquine or primaquine to treatments of active plus dormant malarials (St.Jean et al, 2016; Lacerda et al, 2019; Llanos-Cuentas et al 2019) is partially effective against both active and dormant phase plasmodia, when neither treatment of active nor dormant disease alone is effective for either in vivo. We developed experiments based on these observations where experiments with tafenoquine alone or with JAG21 alone was used in the experiments with established cyst with immune competent mice. This was to determine whether tafenoquine might add to efficacy of JAG21. The efficacy of treatment with JAG21 alone was so robust (Fig. 5B), that no additive effect was seen, or could have been detected, by adding Tafenoquine to JAG21. Efficacy was shown when data were analyzed as separate groups, i.e., control vs JAG21 alone (p<0.03) or control vs JAG21 plus tafenoquine, or grouping the JAG21 and JAG21 plus tafenoquine results as “untreated” versus “treated” (p<0.01). Analysis shown combining both treatment groups from two replicate experiments showed similar results (p<0.01). (Fig 5B), and when results from replicate experiments were grouped (Supplemental Fig S1). In Fig 5C the control mice had cysts with usual morphology (Top two panels), whereas treated mice had very few morphologically recognizable usual cysts that were immunostained (bottom panels).

A nano formulation homogenized (<6 μM) was used effectively orally for the P.berghei experiments, further, importantly, was effective in the single oral dose causal prophylaxis in 5 C57BL/6 albino mice at 2.5 mg/kg dosed on day 0, 1 hour after intravenous administration of 10,000 P. berghei sporozoites was completely protective. In addition, 3 dose causal prophylaxis treatment in 5 C57BL/6 albino mice at 0.625 mg/kg dosed on days -1, 0, and +1 also was completely protective. A representative experiment at a higher dose (5 mg/kg) is shown, but all experiments with the oral dosing regimen with the nanoformulation specified above showed 100% survival 30 days post infection with P. berghei, where all liver and blood stage parasites were eliminated (Fig. 5D,E) demonstrates not only efficacy of JAG21 against the three life cycle stages of P. berghei, but also demonstrates the efficacy of oral administration of the nanoformulation when used immediatel, at a low dose.

G1 Arrest, Persisters, Companion Compounds

In mice that were treated with JAG21 early after infection (Fig 5A) we could find no residual immunostaining for T.gondii in brain tissue of any mice. This suggests that very early treatment could prevent established, chronic infection, for example in epidemics such as those that occurred in Victoria, Canada, the U.S.A., and Brazil. In mice with established cysts, following treatment with JAG21, we occasionally saw a small number of cysts (Fig 5B) and amorphous immunostained structures (Fig. 5C bottom panels). This was reminiscent of persistence in some malaria infections (Cubi et al, 2017) and abnormal immunostained structures we previously identified with a conditional, tetracycline-on regulatable, mutant T.gondii (Hutson et al, 2010 and Fog.S2). In this ΔRPS13 tachyzoite, small ribosomal protein 13 can be regulated, depending on whether anhydrotetracycline (ATc) is absent or present, leading the ATc responsive repressor to be on or
off response elements engineered into the promoter (Hutson et al, 2010). ΔRPS13 replicates with ATc present and is arrested in G1 when ATc is absent in HFF cultures (Hutson et al, 2010). The dormant parasite could persist for extended periods (Hutson et al, 2010). The parasite could be rescued from its dormant – ATc state by adding ATc, months after removing tetracycline from infected HFF cultures, although it could not be rescued in immunocompetent mice with LNAME and ATc when tested one week after infection (Hutson et al, 2010). We wondered if this type of dormant organism could form in vivo, whether it could contribute in a biologically relevant way to dormancy and recrudescence, similar to the malaria hypnozoite, and whether JAG 21 might be able to eliminate it, or whether a companion compound effective against this form might be needed or work in conjunction with JAG21 if needed. To begin to address these questions and to investigate how close the T. gondii ΔRPS13 -ATc phenotype might be to the malaria hypnozoite, we compared the transcriptome of T. gondii ΔRPS13 in human, primary, brain, neuronal stem cells +/-ATc to the recently published P. cynomolgi hypnozoite transcriptome established with single cell RNA sequencing in laser captured organisms (Cubi et al, 2017). This analysis identified 28 orthologous genes with similar expression pattern in both T. gondii ΔRPS13 -ATc and P. cynomolgi hypnozoites, including the downregulation of rps13 and upregulation of the eukaryotic initiation factor-2α kinase IF2K-B, a protein involved in translational control in response to stress (Cubi et al 2017) (Fig 6A). Further, assessment of the T. gondii ΔRPS13 transcriptome in the absence or presence of ATc showed upregulation of additional IF2K members, 25 Apetela (AP) 2 transcription factors and a number of genes that participate as protein ubiquitin ligases, and in trafficking as well as in RNA binding (Supplemental Table S2). None of them, except for AP2VIIa-7, have been shown to be upregulated nor downregulated during differentiation to bradyzoites. Gene set enrichment analysis showed that in the absence of ATc, the T. gondii ΔRPS13 transcriptome is enriched in genes typically expressed during G1, confirming previous results indicating that downregulation of rps13 arrests the parasite at this stage of the cell cycle (Fig. 6B) (Hutson et al, 2010). Moreover, a number of biological processes are downregulated without ATc, including protein synthesis and degradation as well as energy metabolism (Fig. 6B). Noteworthy, some gene ontology (GO) terms enriched in T. gondii ΔRPS13 -Tc are also overrepresented in the P. cynomolgi hypnozoite (stars in Fig. 6D). Further, without ATc the transcriptome of T. gondii ΔRPS13 is compatible with a parasite transitioning from an active replicating form to a dormant stage, reflected by the downregulation of genes typical of the S and M stages of the cell cycle, and of genes that participate in energy metabolism and virulence (Fig. 6B, D, and Supplemental Table S2 and Fig S2). It has been reported that with treatment of active forms of malaria, hypnozoites still persist, and recrudesces later (Cubi et al, 2017, Hutson et al 2010; St.Jean et al, 2016; Lacerda et al, 2019; Llanos-Cuestas et al, 2019). Also, compounds that target cytochrome b/c were not effective against malaria hypnozoites. If primaquine or tafenoquine, which do not treat the active P. vivax parasites, were added in vivo, hypnozoites have been shown not to recrudesce, or do so less often (St. Jean et al, 2016; Lacerda et al, 2019; Llanos-Cuestas et al, 2019). Testing with primaquine or tafenoquine could only be performed in vivo, as activity against the hypnozoite requires hepatic metabolism of primaquine or tafenoquine (St.Jean et al 2016; Lacerda et al, 2019; Llanos-Cuestas et al, 2019). Tafenoquine is not active in tissue culture which is consistent with the findings that these compounds require hepatic metabolism. To establish a parallel in vivo system, we studied immune compromised mice (Interferon Y receptor knockout mice with the knockout in the germline) infected with ΔRPS13 herein. Although in immune competent mice ΔRPS13 does not recrudesce with ATc treatment beyond 3 days after infection, we found that when ATc was added after treatment of the immune compromised mice
with JAG21 dosed intraperitoneally for 14 days, the dormant ΔRPS13 parasite could still recrudesce after JAG21 treatment was discontinued and tetracycline added (Fig. 6C, Supplemental Fig. S2). Consistent with adding tafenoquine to treatment of *P. vivax* malaria with chloroquine where both medicines together were partially effective against the active and hypnozoite forms, the combination of JAG21 and tafenoquine had a modest effect together on transiently improving survival time when ATc was added when compared with JAG21 or tafenoquine alone (Fig 6C, Supplemental Fig. S2). The trend in the result seems similar to the malaria infections where hypnozoites form, although protection was not as robust, as in the malaria model, and we did not achieve complete, durable protection against ΔRPS13. These results in Figures 6C and S2 suggest: a. In G1 arrested organisms that begin as tachyzoites, they can persist in vivo even if their morphology as parasites is difficult to discern; b. Treatment with JAG21 + Tafenoquine can prolong time to death more robustly than other treatments; c. But, in these immune compromised mice at this dosage regimen this treatment did not robustly, durably protect these mice from death later; d. In these immune compromised mice, whether this lack of complete protection was because of immune compromise, or less than optimal duration of treatment, or suboptimal dose or timing of treatments, or that this G1 arrested organism is harder to treat, remains to be determined in future studies. The modest efficacy of the two compounds, administered together, suggests that treating both tachyzoites and the G1 arrested organisms is important. This seems similar to *P. cynomolgi* and *P. vivax* treatment with tafenoquine and chloroquine studies, which also showed efficacy but was not completely successful in preventing relapse. At the time this study was performed, formulation and dosing (including duration and timing) had not yet been optimized formally for the *T. gondii* model. *P. vivax* treatment requires chloroquine to treat blood schizonts and tafenoquine to treat hypnozoites. Treatment in man, per the FDA approved label, consists of a single dose of 300 mg on day 1 co-administered with chloroquine treatment on days 1 or 2. Both medicines have long half-lives in humans. This treatment was relatively effective in humans, with about a 30% recurrence rate.

Sinai et al have demonstrated heterogeneity in the phenotypes of organisms within established cysts. Their work found bradyzoites within cysts are not uniform with regard to their replication potential (Watts et al, 2015), mitochondrial activity (Sinai, unpublished), and levels of the glucose storage polymer amylopectin (Sinai, unpublished). These properties of bradyzoites within (Watts, et al, 2015), and properties of tissue cysts vary during the course of infection with unappreciated levels of complexity in the progression of chronic toxoplasmosis (Watts et al, 2015). The analysis (Fig 6D) of the ΔRPS13 infected NSC suggests molecular targets modified in this G1 arrested ΔRPS13 parasite as shown in Fig 6D Supplemental Table S2. In the future, with formulation and pharmacokinetics of JAG21 optimized, it will be of interest to determine whether JAG21 can eliminate these organisms and any residual structures as in Fig 6C, or whether adding synergistic compounds such as atovaquone (Fig 4B) or antisense effective against these upregulated molecular targets, such as kinases, ATPases, AP2s (Fig 6D and Table S2), or a newly recognized bradyzoite master regulator of differentiation might be effective alone or might be synergistic with JAG21 against this ΔRPS13, as well as the conventional recognized tachyzoite and bradyzoite life cycle stages. Chen et al reported in the transcriptomes of established bradyzoite in vivo cysts that EIF2 kinase of stressed parasites is present (Chen et al, 2018), but we have not found other overlap of Chen’s transcriptome with *P cynomolgi* or ΔRPS13 transcriptomes. Others have described EIF2 kinase and stress granules only in transitioning or extracellular parasites (Watts et al, 2015). Bradyzoites within tissue cysts are not monolithic, so in future studies single cell RNA sequencing of bradyzoites obtained by laser capture of bradyzoites in vivo defined on the basis of their...
physiological state, may be needed to determine whether a transcriptome signature similar to
\( \Delta \text{RPS13} \) is sometimes present, linked to morphologic/immunostaining features that might
functionally distinguish them to define the character of a hypnozoite-like state in \( T.gondii \). We
noted herogeneity of parasite phenotype, even in the same vacuoles In our earlier IFA and
electron microscopic characterization of G1 arrested \( \Delta \text{RPS13} \) in HFF (Hutson et al, 2010). Heterogeneity also was found very recently in tachyzoites and bradyzoites created by
alkaline conditions in culture across the cell cycle in vitro in HFF, using single cell RNA
sequencing (Xue et al Biornx, 6/3/2019 In Press). These authors also noted that what had
been interpreted as “noise” earlier was found actually to be signal in a more complex environment.
These authors suggest that such heterogeneity might make developing curative treatments more
complex. Our analysis of JAG21 effects and the \( \Delta \text{RPS13} \)-ATet knockdown herein begin to help
address this question: We noted that consistent with heterogeneity in our IFAs, in our comparison
with the Xue et al’s heterogeneous P1-6 clusters analysis, we found that most of the up- or down-
regulated genes are within P3-P5 tachyzoite clusters. Also, consistent with the heterogeneity we
observed in our G1 arrested \( \Delta \text{RPS13} \)-ATet comparison, \( \Delta \text{RPS13} \) has a drop in SAG1 and elevated
SRS44 that is consistent with a brady-like phenotype. BAG1 expression was too low overall to
draw any conclusion about BAG1. It is also noteworthy that in our -ATet relative to +Atet
conditions in primary, human, brain, neuronal stem cells, the master regulator of bradyzoite
differentiation is slightly overexpressed (Log2 Fold Change=0.7, adjusted p-value=0.043).
Although JAG21 is highly potent against tachyzoites and bradyzoites, it did not eliminate every
long-established encysted bradyzoite or -ATet \( \Delta \text{RPS13} \) completely either in vitro or in IFN\( \gamma \)
knock-out mice in vivo. Consistent with heterogeneity, herein JAG21 treatment of \( \Delta \text{RPS13} \) and
transcriptomics analyses define a metabolically quiescent, persist, “stasis” state that is reversible
even after substantial periods of dormancy, that contribute to conceptual and functional
understanding of both Plasmodia species and \( T. gondii \) infections and molecular mechanisms
whereby “persisters” might be eliminated.

An oral nanoformulation is potent against virulent RH
To further develop JAG21 for practical, clinical use, our next step was to make a formulation that
is stable at room temperature, and would be effective when administered orally: Following a
number of unsuccessful alternative methods (data not shown, a dispersion of JAG21 was prepared
using hydroxyethyl cellulose (HEC) and Tween 80. This new formulation method is described in
the Materials and Methods. When this dispersion was imaged using a Nikon ECLIPSE E200
optical microscope set to 40x magnification, the average particle size of the JAG21 dispersion in
HEC/Tween 80 was determined using an in-house image analysis program and was found to be
2.85\( \mu \text{m} \) (Fig 7A). Material was re-sonicated the same way just prior to administration after being
stored for 6 months and retained the same properties (Fig 7A) when imaged. Following
administration of 2,000 highly virulent RH Strain tachyzoites intraperitoneally, the oral
nanoformulation was administered by gavage using a 21 gauge needle. This was given either (1)
as a single dose of 5, 10, or 20mg/kg, or (2) three daily doses of 10mg/kg given for the first three
days after infection. After 5 days the RH strain tachyzoites in peritoneal fluid of each mouse were
quantitated by measurement of YFP they expressed using a fluorimeter and by quantitating parasites
present in peritoneal fluid using a hemocytometer. Parasite burden was reduced by ~60% 5 days
later following the single doses of 10 and 20mg/kg (representative experiment with 10mg/kg
shown in Fig.7B; p<0.03) and markedly reduced with three doses of 10mg/kg administered on
each of the first three days after intraperitoneal injection of the virulent RH strain tachyzoites
DISCUSSION

*T. gondii* infections are highly prevalent and the impact of this disease can be devastatingly severe. Current treatments have toxicity or hypersensitivity side effects. New compounds that are without toxicity or hypersensitivity, and that are highly active against tachyzoites would be of considerable clinical usefulness. Further, no medicines are active against the encysted stage or definitively curative. In addition, malaria is lethal for 1 child every eleven seconds and a threat to travelers going to endemic areas. Development of drug resistance also increases the need for new antimalarial compounds. Our goal in this work herein was to identify compounds highly effective against *T. gondii* and *Plasmodium* species, and we believe we have achieved our goal by developing lead compounds with dual activity.

To further develop the THQ series, 54 compounds were synthesized to improve kinetic solubility, solubility in physiologically-relevant media (FaSSIF, FeSSIF), and metabolic stability (microsomes and hepatocytes), and other ADMET properties. Compounds JAG050 and JAG021 were identified as lead compounds, demonstrating potent inhibition on both tachyzoites and bradyzoites life stages and were not toxic to human cells in our *in vitro* model (HFF). In addition, both compounds displayed low nanomolar efficacy against multiple drug resistant strains of *P. falciparum in vitro*. JAG050 and JAG021 demonstrate promising ADMET properties, with JAG21 slight superior due to the compound's longer metabolic stability in human and mouse microsomes.

A striking result with JAG21 in our *in vivo* parasite studies is the compound's high efficacy against *T. gondii* tachyzoites and bradyzoites. In our *P. berghei in vivo* model for malaria, we observed that a single dose causal prophylaxis in 5 C57BL/6 albino mice at 2.5 mpk dosed on day 0, 1 hour after intravenous administration of 10,000 *P. berghei* sporozoites was achieved. Causal prophylaxis was also observed after a 3-dose treatment in 5 C57BL/6 albino mice at 0.6 mpk dosed on days -1, 0, and +1. A representative figure at a higher dose (5 mg/kg) is shown, and all experiments with the amounts mentioned above demonstrated identical high efficacy in luminescence, parasitemia, and survival results. This demonstrates that JAG21 functions better in this *in vivo* model than the ELQ 300 series where prodrug formulation is required to achieve solubility and efficacy In contrast to the efficacy of JAG21 at 2.5mg/kg in a single oral dose model resulting in cure without a prodrug. ELQ 300 (not the prodrug) was not effective at doses between 1 and 20 mg/kg although the prodrug was more effective (Doggett, et al 2012; Freuh et al, 2017).

JAG050 and JAG021 are lead compounds, with JAG21 being a superior compound due to its favorable predicted ADMET properties, potency, efficacy and lack of toxicity. JAG021 demonstrates increased solubility and potential for advanced formulation. There also is potential for improving solubility and reducing toxicity further because of the larger binding pocket in the apicomplexan Cytc1 enzyme compared with the mammalian Cytc1 enzyme, determined by modeling occupancy of the structure, enzyme assays and empirically, if it were needed. We have created and tested additional compounds that take advantage of these properties, although none at present, have the proven ADMET and marked *in vivo* efficacy we found to be advantages in our proof of principle studies of JAG21. At present, however, our mature lead compound has sufficient drug like properties to move to advanced formulations, suggesting increased bulk will not be needed to reduce toxicity. It has selectivity as demonstrated by our enzymatic, binding and
structure studies, although there are additional compounds that show even greater selectivity. It is highly effective in an oral nano preparation against *P. berghei* three life cycle stages, and with early treatment appears to be capable of curing toxoplasmosis in immunocompetent mice. This work demonstrates the promising nature of this novel tetrahydroquinolone scaffold and mature lead compound. JAG21 has the potential to become an orally administered medicine or with partners, part of a medicine combination that is curative for toxoplasmosis and is a single dose cure for malaria. It is suitable for partnering with other compounds to obviate problems with selection of resistant mutants. We have demonstrated earlier that the parent compound with this new scaffold is synergistic with atovaquone and additive with cycloguanil (in proguanil) against *P. falciparum* (McPhillie et al, 2016). This compound is a mature lead compound to treat both *T.gondii* and Plasmodium species infections. If utility and safety is retained and no toxicity appears in next stage studies, this compound may become suitable for treatment of *T. gondii* and *P. falciparum* infections.

**CONCLUSION**

JAG21 has real promise as a mature lead compound to treat both *T.gondii* and Plasmodium species infections, demonstrated *in vitro* and *in vivo*. It has high efficacy against *T.gondii* tachyzoites and bradyzoites, and established encysted organisms. Treatment with a single low oral dose is effective for causal prophylaxis and radical cure of *P.berghei* infections. JAG 21 has complete efficacy against three life cycle stages of *P.berghei*. In terms of companion inhibitors, JAG21, a Q$_i$ inhibitor, synergizes against tachyzoites with atovaquone (a Q$_o$ inhibitor) *in vitro*. It appears able to contribute modestly to protection of immune compromised mice in conjunction with tafenoquine against an initially replicating, then G1 arrested, *T.gondii* parasite that shares key transcriptomic components with *P. cynomolgi* hypnozoites. Our mature lead compound has sufficient selectivity and drug-like properties to support ongoing efforts to further develop this compound through preparation of advanced formulations and testing of additional study of pharmacokinetics, efficacy and safety.

**ETHICS STATEMENT**

This study was carried out in accordance with regulations of The University of Chicago IACUC and IBC and of The Home Office of the UK Government under the Animals [Scientific Procedures] Act 1986. All work in the UK with mice was covered by License PPL60/4568, Treatment and Prevention of Toxoplasmosis with approval by the University of Strathclyde ethical review board.

Qi and Qo sites are marked by black ellipsoids. C. The bound JAG021 compound (orange) within the Qi site with corresponding (2Fo-Fc) electron density map contoured at 1σ level as grey mesh. The residues which make close interactions with the bound inhibitor are shown in stick format and labelled. D. 2D pharmacophore analysis of JAG021 binding pocket produced using Ligplot+ LS-2011. Hydrophobic interactions are shown as red spikes, hydrogen bond with Ser35 is shown by green dashes. E. Cryo-EM derived structure of the Cytbc1 bound JAG021 structure with corresponding density map contoured at 3σ level suggesting two different positions for the head group represented by two regions of density shown as yellow mesh. The Cytbc1 structure bound to the pyridone GSK932121 (PDB:4D6U) (F) and quinolone MJM170 (PDB:5NMI) (G) in the Qi site. Haem and compounds are shown as colored sticks, Fe ion as orange sphere and hydrogen bonding as black lines. Hydrogen bonding with Ser35 is shown as black dashes.

Figure 5. JAG21 is a mature lead that protects against T. gondii and P.berghei in vivo. A. JAG21 treatment for 14 days protects against T.gondii tachyzoites in vivo. Tachyzoite challenge with Prugneaud luciferase parasites imaged with leuciferin using IVIS demonstrates that treatment with JAG21 eliminates leuciferase expressing parasites and leads to 100% survival of JAG21 treated infected mice. No cysts were found in brains of mice at 30 days after infection.
when they have been treated with JAG21 for the first 14 days after infection. There were 2 biological replicate experiments with 5 mice per group with similar results. **B. JAG21 and JAG21 plus tafenoquine markedly reduce Me49 strain brain cyst numbers *in vivo* in Balb/C mice at 30 days after infection.** Parasites were quantitated by scanning the entire immunoperoxidase stained slide in an automated manner and by two observers blinded to the experimental treatment using microscopic evaluation. In each of two experiments, the numbers of mice per group were as follows: Experiment 1 had 4 diluent controls, 5 JAG21, 4 JAG21/Tafenoquine treated mice; and Experiment 2 had 5 diluent controls, 5 JAG21, 3 JAG21/Tafenoquine treated mice. Immunoperoxidase staining was performed. Parasite burden was quantitated using a positive pixel count algorithm of Aperio ImageScope software. Positive pixels were normalized to tissue area (mm$^2$). Quantification was by counting positive pixels per square area. The entire brain in one section was scanned for each mouse. The parasite burden was quantitated as units of positive pixels per mm$^2$. The average +/- S.E.M. numbers of mm$^2$ per slide quantitated was 30.2 +/- 1.6 mm$^2$ per mouse for this quantification. Each high power field of view shown in C is approximately 0.02 mm$^2$ per field of view. A representative single experiment is presented and the data from the two experiments analyzed together also demonstrated significant differences between the untreated and treated groups (p<0.01; Supplemental **Fig. S1.**). **C. Microscopic evaluation of the slides** reveal effect of JAG21 and JAG21 plus tafenoquine having the same pattern as the automated quantitation of immunoperoxidase stained material. There are usual appearing cysts in the DMSO control untreated mice as shown in the top panels, and rare cysts in the treated mice with most of the brown material appearing amorphous (bottom panels). **D. JAG21 nanoformulation dosages administered to P.berghei infected C57Bl6/albino mice compared with vehicle control.** Design of single dose and 3 day dose experiments. **E. JAG21**
nanoformulation cures *P. berghei* sporozoites(c), blood(d) and liver stages(e) with oral administration of a single dose of 2.5mg/kg or 3 doses at 0.625mg/kg. Single dose causal prophylaxis in 5 C57BL/6 albino mice at 2.5 mpk dosed on day 0, 1 hour after intravenous administration of 10,000 *P. berghei* sporozoites. Shown is 3 dose causal prophylaxis treatment in 5 C57BL/6 albino mice at 0.625 mpk dosed on days -1, 0, and +1. Representative figure showing survival, luminescence and parasitemia quantitated by flow cytometry for 5 mg/kg.

**Figure 6.** *T. gondii* ΔRPS13 transcriptome during Primary Human Brain Neuronal Stem Cell (NSC) infection and *in-vivo* susceptibility to JAG21 and TAF treatment are reminiscent of literature findings with malaria hypnozoites. A, *P. cynomolgi-T. gondii* best reciprocal match genes significantly upregulated (red) or downregulated (blue) in *P. cynomolgi* hypnozoites compared to liver-schizont stage and in ΔRPS13 after downregulation of rps13 gene expression (p-value ≤ 0.05, FDR ≤ 0.2). B, Gene-set enrichment analysis of ΔRPS13 +/-Tc. Blue and red nodes denote gene-sets enriched in presence or absence of Tc respectively. Node diameters are proportional to number of genes belonging to corresponding gene-sets. Edge thickness is proportional to number of genes shared between connected nodes. C, Survival rate of mice infected with 100,000 ΔRPS13 followed by treatment with diluent, JAG21, tafenoquine (TAF) or the two together (JAG21/TAF). Then tetracycline was added at 14 days. The combination of the two compounds resulted in improved time of survival (p<0.03, Experiment 1; p=0.08 Experiment 2, p=0.002 Experiment 1+2). The full data are presented in the box below the image in Fig 6C. In 6C, Rx refers to treatment of mice with diluent (DMSO), Tafenoquine (TAF), or JAG21, or JAG21 and TAF. ΔRPS13 is referred to as RhRPS13Δ in the title of the box in Fig 6C. In Supplemental Fig S2, histological preparations that are immunoperoxidase stained for *T. gondii* antigens from a
pilot study were prepared (Supplemental Fig. S2). These are images, in Fig S2 of liver and spleen from IFN γ receptor knock out mice without treatment on days 7 and 14 after infection. In those mice without any treatment there was amorphous brown immunoperoxidase stained material in Fig S2 A. When tetracycline (aTet) was administered on day 14 after infection in drinking water on day 14 and tissues obtained and immunostained for T. gondii antigens from mice that died or became very ill, organisms clearly recognizable could be seen (Supplemental Fig S2B-E). Design of the treatment experiment with control DMSO diluent, JAG21 alone, Tafenoquine alone (TAF) or the two together (JAG/TAF) with full data for each of the groups and with the composite analysis from replicate experiments, including numbers of mice, are shown in supplemental Fig. S2C, D. Fig S2 C, D shows prolongation of survival time, but there is not durable protection against ∆RPS13 in these immune compromised mice treated with JAG21/TAF as described. This is summarized in C to demonstrate early prolongation of survival time with the detailed data in Fig S2. D. Gene ontology enrichment analysis of ∆RPS13 +/-Tc. Node and edge conventions are the same as in B. There were at least 2 biologic replicates of each experiment.

Figure 7. Oral nanoformulation of JAG21 potently protects against 2000 highly virulent RH strain tachyzoites given intraperitoneally. A. Following sonication produces nanoparticles of ~2.86microM. B. Single oral dose of 10mg/kg reduced intraperitoneal tachyzoites measured by RH YFP expression and counting with hematocytometer(p<0.03),. C. Three daily 10mg/kg doses markedly and significantly reduces intraperitoneal parasite burden measured as fluorescence and by hematocytometer on the fifth day(p<0.001).No compound was administered after the third day. N=at least 2 biological replicate experiments with 5 mice per group with similar results.
