ABSTRACT

Background

Debates on effective and safe diets for managing obesity in adults are ongoing. Low-carbohydrate weight-reducing diets (also known as 'low-carb diets') continue to be widely promoted, marketed and commercialised as being more effective for weight loss, and healthier, than 'balanced'-carbohydrate weight-reducing diets.

Objectives

To compare the effects of low-carbohydrate weight-reducing diets to weight-reducing diets with balanced ranges of carbohydrates, in relation to changes in weight and cardiovascular risk, in overweight and obese adults without and with type 2 diabetes mellitus (T2DM).

Search methods

We searched MEDLINE (PubMed), Embase (Ovid), the Cochrane Central Register of Controlled Trials (CENTRAL), Web of Science Core Collection (Clarivate Analytics), ClinicalTrials.gov and WHO International Clinical Trials Registry Platform (ICTRP) up to 25 June 2021, and screened reference lists of included trials and relevant systematic reviews. Language or publication restrictions were not applied.

Selection criteria

We included randomised controlled trials (RCTs) in adults (18 years+) who were overweight or living with obesity, without or with T2DM, and without or with cardiovascular conditions or risk factors. Trials had to compare low-carbohydrate weight-reducing diets to balanced-carbohydrate (45% to 65% of total energy (TE)) weight-reducing diets, have a weight-reducing phase of 2 weeks or longer and be explicitly implemented for the primary purpose of reducing weight, with or without advice to restrict energy intake.

Data collection and analysis

Two review authors independently screened titles and abstracts and full-text articles to determine eligibility; and independently extracted data, assessed risk of bias using RoB 2 and assessed the certainty of the evidence using GRADE. We stratified analyses by participants without and with T2DM, and by diets with weight-reducing phases only and those with weight-reducing phases followed by weight-maintenance phases. Primary outcomes were change in body weight (kg) and the number of participants per group with weight loss of at least 5%, assessed at short- (three months to < 12 months) and long-term (≥ 12 months) follow-up.

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

Main results

We included 61 parallel-arm RCTs that randomised 6925 participants to either low-carbohydrate or balanced-carbohydrate weight-reducing diets. All trials were conducted in high-income countries except for one in China. Most participants ($n = 5118$ randomised) did not have T2DM. Mean baseline weight across trials was 95 kg (range 66 to 132 kg). Participants with T2DM were older (mean 57 years, range 50 to 65) than those without T2DM (mean 45 years, range 22 to 62). Most trials included men and women (42/61; 3/19 men only; 16/19 women only), and people without baseline cardiovascular conditions, risk factors or events (36/61). Mean baseline diastolic blood pressure (DBP) and low-density lipoprotein (LDL) cholesterol across trials were within normal ranges. The longest weight-reducing phase of diets was two years in participants without and with T2DM. Evidence from studies with weight-reducing phases followed by weight-maintenance phases was limited.

Most trials investigated low-carbohydrate diets (> 50 g to 150 g per day or $< 45\%$ of TE; $n = 42$), followed by very low (≤ 50 g per day or $< 10\%$ of TE; $n = 14$), and then incremental increases from very low to low ($n = 5$). The most common diets compared were low-carbohydrate, balanced-fat (20 to 35% of TE) and high-protein ($> 20\%$ of TE) treatment diets versus control diets balanced for the three macronutrients (24/61). In most trials (45/61) the energy prescription or approach used to restrict energy intake was similar in both groups. We assessed the overall risk of bias of outcomes across trials as predominantly high, mostly from bias due to missing outcome data. Using GRADE, we assessed the certainty of evidence as moderate to very low across outcomes.

Participants without and with T2DM lost weight when following weight-reducing phases of both diets at the short (range: 12.2 to 0.33 kg) and long term (range: 13.1 to 1.7 kg).

In overweight and obese participants without T2DM: low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets (weight-reducing phases only) probably result in little to no difference in change in body weight over three to 8.5 months (mean difference (MD) -1.07 kg, 95% confidence interval (CI) -1.55 to -0.59 , $I^2 = 51\%$, 3286 participants, 37 RCTs, moderate-certainty evidence) and over one to two years (MD -0.93 kg, 95% CI -1.81 to -0.04 , $I^2 = 40\%$, 1805 participants, 14 RCTs, moderate-certainty evidence); as well as change in DBP and LDL cholesterol over one to two years. The evidence is very uncertain about whether there is a difference in the number of participants per group with weight loss of at least 5% at one year (risk ratio (RR) 1.11, 95% CI 0.94 to 1.31, $I^2 = 17\%$, 137 participants, 2 RCTs, very low-certainty evidence).

In overweight and obese participants with T2DM: low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets (weight-reducing phases only) probably result in little to no difference in change in body weight over three to six months (MD -1.26 kg, 95% CI -2.44 to -0.09 , $I^2 = 47\%$, 1114 participants, 14 RCTs, moderate-certainty evidence) and over one to two years (MD -0.33 kg, 95% CI -2.13 to 1.46, $I^2 = 10\%$, 813 participants, 7 RCTs, moderate-certainty evidence); as well in change in DBP, HbA1c and LDL cholesterol over 1 to 2 years. The evidence is very uncertain about whether there is a difference in the number of participants per group with weight loss of at least 5% at one to two years (RR 0.90, 95% CI 0.68 to 1.20, $I^2 = 0\%$, 106 participants, 2 RCTs, very low-certainty evidence).

Evidence on participant-reported adverse effects was limited, and we could not draw any conclusions about these.

Authors' conclusions

There is probably little to no difference in weight reduction and changes in cardiovascular risk factors up to two years' follow-up, when overweight and obese participants without and with T2DM are randomised to either low-carbohydrate or balanced-carbohydrate weight-reducing diets.

PLAIN LANGUAGE SUMMARY

Low-carbohydrate diets or balanced-carbohydrate diets: which works better for weight loss and heart disease risks?

Key messages

- There is probably little to no difference in the weight lost by people following low-carbohydrate weight-reducing diets (also known as 'low-carb diets') compared to the weight lost by people following balanced-carbohydrate weight-reducing diets, for up to two years.
- Similarly, there is probably little to no difference between the diets for changes in heart disease risks, like diastolic blood pressure, glycosylated haemoglobin (HbA1c, a measure of blood sugar levels over 2-3 months) and LDL cholesterol ('unhealthy' cholesterol) up to two years.
- This was the case in people with and without type 2 diabetes.

What are low-carbohydrate and balanced-carbohydrate weight-reducing diets?

People spend lots of money on trying to lose weight using diets, products, foods and books, and continue to debate about which diets are effective and safe. So, examining the scientific evidence behind claims made is important. Low-carbohydrate diets are a broad category of weight-reducing diets that manipulate and restrict carbohydrates, protein and fat in diets. There are no consistent, widely-accepted

definitions of these diets and different descriptions are used (such as, 'low-carbohydrate, high-protein', 'low-carbohydrate, high-fat', or 'very low-carbohydrate').

Low-carbohydrate diets are implemented in different ways, but they restrict grains, cereals and legumes, and other carbohydrate-containing foods; such as dairy, most fruit and certain vegetables. These foods are then typically replaced with foods higher in fat and protein; such as meats, eggs, cheese, butter, cream, oils. Some low-carbohydrate diets recommend eating as desired, while others recommend restricting the amount of energy eaten.

Balanced-carbohydrate diets contain more moderate amounts of carbohydrates, protein and fats, in line with current healthy eating advice from health authorities. When used for weight reduction, balanced diets recommend restricting the amount of energy eaten by guiding people to reduce their portion sizes and choose healthier foods (e.g. lean instead of fatty meat).

Low-carbohydrate weight-reducing diets are widely promoted, marketed and commercialised as being more effective for weight loss, and healthier, than 'balanced'-carbohydrate weight-reducing diets.

What did we want to find out?

We wanted to find out if low-carbohydrate weight-reducing diets were better for weight loss and heart disease risk factors than balanced-carbohydrate weight-reducing diets in adults who were overweight or living with obesity.

We wanted to find this out for people with and without type 2 diabetes.

What did we do?

We searched six electronic databases and trial registries for all trials* that compared low-carbohydrate weight-reducing diets with balanced-carbohydrate weight-reducing diets in adults who were overweight or living with obesity. The trials had to last for at least three months. We compared and summarised the results of the trials and rated our confidence in the combined evidence, based on factors such as study methods and sizes.

*A trial is a type of study in which participants are assigned randomly to two or more treatment groups. This is the best way to ensure similar groups of participants.

What did we find?

We found 61 trials involving 6925 people who were overweight or living with obesity. The biggest trial was in 419 people and the smallest was in 20 people. All except one of the trials were conducted in high-income countries worldwide, and nearly half were undertaken in the USA (26). Most trials (36) were undertaken in people who did not have heart disease or risk factors. Most people (5118 people) did not have type 2 diabetes. The average starting weight of people across the trials was 95 kg. Most studies (37) lasted for six months or less; and the longest studies (6) lasted for two years.

Main results

Low-carbohydrate weight-reducing diets probably result in little to no difference in weight loss over the short term (trials lasting 3 to 8.5 months) and long term (trials lasting one to two years) compared to balanced-carbohydrate weight-reducing diets, in people with and without type 2 diabetes. In the short term, the average difference in weight loss was about 1 kg and in the long term, the average difference was less than 1 kg.

People lost weight on both diets in some trials. The amount of weight lost on average varied greatly with both diets across the trials from less than 1 kg in some trials and up to about 12 kg in others in the short term and long term.

Similarly, low-carbohydrate weight-reducing diets probably result in little to no difference in diastolic blood pressure, glycosylated haemoglobin (HbA1c) and LDL cholesterol ('unhealthy' cholesterol) for up to two years.

We could not draw any conclusions about unwanted effects reported by participants because very few trials reported these.

What are the limitations of the evidence?

We are moderately confident in the evidence. Our confidence was lowered mainly because of concerns about how some the trials were conducted, which included that many trials did not report all their results. Further research may change these results.

How up to date is this evidence?

The evidence is up-to-date to June 2021.

SUMMARY OF FINDINGS

Summary of findings 1. Summary of findings table - Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (weight-reducing phase only)

Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (weight-reducing phase only)

Patient or population: overweight and obese participants without T2DM (weight-reducing phase only)

Setting: outpatient clinics, medical/research centres in high-income countries

Intervention: low-carbohydrate weight-reducing diets

Comparison: balanced-carbohydrate weight-reducing diets

Outcomes	Anticipated absolute effects* (95% CI)		Relative effect (95% CI)	Nº of participants (studies)	Certainty of the evidence (GRADE)	Comments
	Risk with balanced-carbohydrate weight-reducing diets	Risk with low-carbohydrate weight-reducing diets				
Change in body weight (kg) at 3 to < 12 months	The mean change in body weight (kg) at 3 to < 12 months ranged from -11.34 to -2.3 kg	MD 1.07 kg lower (1.55 lower to 0.59 lower)	-	3286 (37 RCTs)	⊕⊕⊕⊖ Moderate ^a	Low-carbohydrate weight-reducing diets probably result in little to no difference in change in weight at 3 to 8.5 months.
Change in body weight (kg) at ≥ 12 months	The mean change in body weight (kg) at ≥ 12 months ranged from -11.6 to -1.7 kg	MD 0.93 kg lower (1.81 lower to 0.04 lower)	-	1805 (14 RCTs)	⊕⊕⊕⊖ Moderate ^a	Low-carbohydrate weight-reducing diets probably result in little to no difference in change in weight (kg) at 1 to 2 years.
Number of participants per group with weight loss of at least 5% at ≥ 12 months	789 per 1000	875 per 1000 (741 to 1000)	RR 1.11 (0.94 to 1.31)	137 (2 RCTs)	⊕⊖⊖⊖ Very low ^{b,c}	The evidence is very uncertain about the effect of low-carbohydrate weight-reducing diets on number of participants per group with weight loss of at least 5% at 1 year.
Cardiovascular mortality - not measured	-	-	-	-	-	
Change in DBP (mmHg) at ≥ 12 months	The mean change in DBP (mmHg) at ≥ 12 months ranged from -11 to 2.9 mmHg	MD 0.09 mmHg lower (1.29 lower to 1.12 higher)	-	1419 (11 RCTs)	⊕⊕⊕⊖ Moderate ^a	Low-carbohydrate weight-reducing diets probably result in little to no difference in change in DBP at 1 to 2 years.

Change in LDL cholesterol (mmol/L) at ≥ 12 months	The mean change in LDL cholesterol (mmol/L) at ≥ 12 months ranged from -0.31 to 0.1 mmol/L	MD 0.04 mmol/L higher (0.05 lower to 0.12 higher)	-	1494 (13 RCTs)	⊕⊕⊕⊖ Moderate ^a	Low-carbohydrate weight-reducing diets probably result in little to no difference in change in LDL cholesterol at 1 to 2 years.
Constipation at 3 to < 12 months	267 per 1000	283 per 1000 (216 to 368)	RR 1.06 (0.81 to 1.38)	564 (4 RCTs)	⊕⊕⊕⊖ Very low ^{a,d}	The evidence is very uncertain about the effect of low-carbohydrate weight-reducing diets on constipation at 3 to 6 months.

***The risk in the intervention group** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: confidence interval; **MD:** mean difference; **RR:** risk ratio

GRADE Working Group grades of evidence

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

See interactive version of this table: https://gdt.gradepro.org/presentations/#/isof/isof_question_revman_web_420942855893718659.

^a Serious risk of bias: The majority of information is from studies at high overall risk of bias

^b Serious risk of bias: All information is from a study at high overall risk of bias

^c Very serious imprecision: OIS not met; 95% CI for the pooled estimate is consistent with the possibility for important benefit (245 per 1000 absolute increase) and unimportant harm (47 per 1000 absolute reduction)

^d Very serious imprecision: OIS not met; 95% CI for the pooled estimate is consistent with the possibility for unimportant benefit (51 per 1000 absolute reduction) and for important harm (101 per 1000 absolute increase)

Summary of findings 2. Summary of findings table - Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (weight-reducing phase followed by weight-maintenance phase)

Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (weight-reducing phase followed by weight-maintenance phase)

Patient or population: overweight and obese participants without T2DM (weight-reducing phase followed by weight maintenance phase)

Cardiovascular mortality - not measured	-	-	-	-	-	
Change in DBP (mmHg) at ≥ 12 months	The mean change in DBP (mmHg) at ≥ 12 months was 0.65 mmHg	MD 0.44 mmHg lower (4.89 lower to 4.01 higher)	-	99 (1 RCT)	⊕⊕⊕⊕ Very low ^{d,e}	The evidence is very uncertain about the effect of low-carbohydrate weight-reducing diets on change in DBP at 1 year.
Change in HbA1c (%) at ≥ 12 months	The mean change in HbA1c (%) at ≥ 12 months ranged from -0.37 to 0.4 %	MD 0.02 % higher (0.3 lower to 0.33 higher)	-	160 (3 RCTs)	⊕⊕⊕⊕ Low ^{b,f}	Low-carbohydrate weight-reducing diets may result in little to no difference in change in HbA1c at 1 to 2 years.

Change in LDL cholesterol (mmol/L) at ≥ 12 months	The mean change in LDL cholesterol (mmol/L) at ≥ 12 months ranged from -0.17 to 0.04 mmol/L	MD 0.06 mmol/L lower (0.26 lower to 0.13 higher)	-	145 (2 RCTs)	⊕⊕⊕⊕ Low ^{b,f}	Low-carbohydrate weight-reducing diets may result in little to no difference in change in LDL cholesterol at 1 to 1.5 years.
Constipation at 3 to < 12 months - not measured	-	-	-	-	-	

***The risk in the intervention group** (and its 95% confidence interval) is based on the assumed risk in the comparison group and the **relative effect** of the intervention (and its 95% CI).

CI: confidence interval; **MD:** mean difference

GRADE Working Group grades of evidence

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

See interactive version of this table: https://gdt.gradepro.org/presentations/#/isof/isof_question_revman_web_421058088671156171.

^a Serious risk of bias: All information is from a study at high overall risk of bias

^b Serious imprecision: OIS not met

^c Serious risk of bias: All information is from studies at high overall risk of bias

^d Serious risk of bias: All information is from a study that has some concerns for overall risk of bias

^e Very serious imprecision: OIS not met; 95% CI for the pooled estimate is consistent with the possibility for important harm and for important benefit

^f Serious risk of bias: All information is from studies at high risk or that have some concerns for overall risk of bias

BACKGROUND

Description of the condition

The 2017 Global Nutrition Report estimates that two billion adults worldwide are overweight or obese, and 41 million children are overweight (Development Initiatives 2017). For the first time in history, more people globally are dying from the consequences of overeating than starvation and malnutrition (Forouzanfar 2015). This shift has happened in the last 20 to 30 years and is thought to be mainly due to diets that are of poor nutritional quality, high in energy density and often ultra-processed. Such diets often result in cumulative weight gain over time and consequently increase the risk of cardiovascular disease, diabetes, stroke and some cancers (Forouzanfar 2015). Globalised food systems promote over-consumption of these foods (Moubarac 2014; Swinburn 2011).

High body mass index (BMI) is an important modifiable risk factor for cardiovascular disease, diabetes, kidney diseases, certain cancers and musculoskeletal conditions (Berrington 2010; ERFC 2011; GBMRF for CD Collaboration 2014; Singh 2013; Whitlock 2009; Zheng 2011). The disease burdens related to obesity are particularly evident in low- and middle-income countries. Cardiovascular disease deaths rose by 12.5% from 15.9 million in 2005 to 17.9 million in 2015, and low- and middle-income countries accounted for over three-quarters of these deaths (GBD MCDC 2016). In Africa, between 1980 and 2014, age-standardised prevalence of type 2 diabetes mellitus (T2DM) increased from 4.8% to 9.7% in men and from 7.7% to 12.6% in women (NCD-RisC 2017). These shifting disease patterns have a major impact on individual and family well-being, and on economies, with large direct and indirect costs being associated with illness.

Description of the intervention

Pharmacotherapy, bariatric surgery and counselling that target diet, physical activity, and behaviour change are used to treat adult obesity (Dietz 2015). Due to the chronic and relapsing nature of obesity and its related conditions, current guidelines for the treatment of obesity recommend comprehensive management approaches that aim to achieve long-term weight reduction. This includes intensive lifestyle intervention characterised by dietary restriction, increased physical activity, and behavioural management as first-line treatment (Dietz 2015; Jensen 2014). Importantly, there is no 'one-size-fits-all' weight-reducing diet and different diets work for different people, based on preferences and ease of adherence (Jensen 2014; Johnston 2014).

The public, families and health professionals face an often dizzying array of weight-reducing diets, many of which have been commercialised as books, seminars, diet food products, supplements and other related products. These include, but are not limited to, various versions of low-carbohydrate diets (for example, Atkins diet (Atkins 1999)), low-fat or so-called 'balanced diets', very low-fat diets (for example, Ornish diet (Ornish 2001)), and low-glycaemic diets (for example, South Beach diet (Agatston 2003)).

Nutrients are needed by the body in small (i.e. micronutrients such as vitamins and minerals) or large amounts (i.e. macronutrients) for growth, repair and optimal functioning (Lichtenstein 2005). Total daily energy intake is made up of the sum of the energy provided by the three macronutrients (i.e. carbohydrate, protein and fat). Per gram of macronutrient, carbohydrates and protein

each provides about 17 kilojoules (approximately 4 kilocalories), while fat provides about 37 kilojoules (approximately 9 kilocalories) (Carreiro 2016). Carbohydrates are primarily contained in grains, cereals and sugar, and in the digestive tract are broken down into glucose. Carbohydrates are the largest nutrient class, and traditionally, the greatest energy source. If energy intake exceeds energy requirements, excess carbohydrates will be mainly stored in the liver as glycogen for later use or be converted to fatty acids when glycogen stores are saturated. In contrast, if the diet contains limited amounts of carbohydrate, the liver converts fat into fatty acids and ketones to replace glucose as an energy source (Paoli 2013).

Low-carbohydrate diets are a broad category of weight-reducing diets and programmes that manipulate and restrict macronutrient (carbohydrate, protein, fat) intake (Astrup 2004; Bazzano 2012; Campbell 2012; Hession 2009). There are no consistent and widely accepted definitions of these diets and different descriptions are used, such as 'low-carbohydrate, high-protein' or 'low-carbohydrate, high-fat', depending on the macronutrient manipulation and focus. In practice, low-carbohydrate diets are applied in different ways, but generally restrict grains, cereals and legumes, and other foods that contain carbohydrates, such as dairy, most fruit and certain vegetables. The energy required is then typically replaced with food higher in fat and protein, such as meats, eggs, cheese, butter, cream and oils - many of which are animal source foods. Some low-carbohydrate diets recommend eating as desired, while others apply restrictions to total energy intake (Atkins 2011; Campbell 2012).

Conventional authorities such as the European Food Safety Authority (EFSA 2017), American Institute of Medicine Food and Nutrition Board (IOM 2005), Australian National Health and Medical Research Council together with the New Zealand Ministry of Health (NHMRC 2006), and the Nordic Council of Ministers, Nordic Committee of Senior Officials for Food Issues (NNR 2012), as well as the UK's Scientific Advisory Committee on Nutrition (SACN 2015), have recommended 45% to 65% of total energy as the appropriate carbohydrate intake for adults. Thus, some people regard low-carbohydrate diets to be those with carbohydrate intakes below 45% of total energy. Some published definitions of low-carbohydrate diets disregard the official recommendations, and use an upper limit of 40% of total energy from carbohydrates as indicative of a low-carbohydrate diet (Frigolet 2011; Wylie-Rosett 2013). In absolute, rather than proportional terms, low-carbohydrate diets have been defined as having less than 200 g of carbohydrate (Frigolet 2011), while some disagree with this liberal definition, preferring to distinguish between 'non-ketogenic low-carbohydrate diets' as containing 50 g to 150 g of carbohydrates, and 'ketogenic low-carbohydrate diets' (or very low-carbohydrate diets) as having a maximum of 50 g of carbohydrates, with this latter variant seen by some as being more effective for weight loss (Westman 2007; Yancy 2004). Ketogenic diets are characterised by a high production of ketones in the liver as an alternative energy source, as well as high levels of ketones in the blood (ketonaemia) and urine (ketonuria) when fat or protein intake is very high and carbohydrate intake is very low (less than 50 g/day) (Paoli 2013).

Weight-reducing diets aligned with current dietary recommendations are often referred to as 'low-fat diets' or 'balanced, weight-reducing diets', and will be referred to as 'balanced diets' in this review (British Dietetic Association

2013). Globally, current dietary recommendations - in terms of macronutrients, micronutrients, food choices and dietary patterns - are generally consistent, and governmental bodies from Europe, the USA, Australia and Nordic countries recommend that 45% to 65% of total energy intake should be provided by carbohydrates, between 10% and 35% by protein and between 20% and 35% by fat (EFSA 2017; IOM 2005; NHMRC 2006; NNR 2012). There is room for flexibility within these ranges from lower to higher intakes of carbohydrate, fat and protein. These dietary recommendations are accompanied by information on 'better food' choices; improving the quality of carbohydrates (e.g. whole grains versus refined grains), protein (e.g. fish versus processed meat) and fat (e.g. olive oil versus butter); as well as on maintaining a healthy body weight by aiming to keep energy intake and energy expenditure balanced.

Nutrition recommendations are moving away from macronutrient-focused, single food and single nutrient messages towards recommendations about dietary patterns and 'total diets' (NICE 2014; NNR 2012; USDA 2014). This has been driven mainly by the lack of clear and consistent associations between individual nutrients (micronutrients and macronutrients) and disease risk, limitations of single nutrient trials, and greater successes of 'total diet' or dietary pattern interventions.

Dietary patterns can be defined as "the quantities, proportions, variety, or combination of different foods, drinks, and nutrients (when available) in diets, and the frequency with which they are habitually consumed" (USDA 2014). Current evidence supports associations between some dietary patterns and lower risk of obesity and chronic diseases, especially T2DM, cardiovascular disease, hypertension, and certain cancers (DGAC 2015; USDA 2014). For example, systematic reviews of large long-term studies show that several dietary patterns are consistently and equally associated with a lower risk of developing T2DM in the future (Alhazmi 2014; Esposito 2014; Koloverou 2014). These dietary patterns have different macronutrient compositions, but share several common components, including fruit, vegetables, whole grains, legumes, nuts, healthy oils, adequate proteins (such as seafood and lean meat), reduced intake of red and processed meats and sugar-sweetened beverages, and little or moderate alcohol (Ndanuko 2016; NNR 2012; USDA 2014). It has been suggested that carbohydrate avoidance and the resultant food restrictions typical of low-carbohydrate diets make it difficult to achieve a dietary pattern that is nutrient- and fibre-rich, diverse, and that promotes good health (USDA 2014).

How the intervention might work

Energy balance and body-weight regulation is complex and interactive, and questions on certain components of energy balance and their interactions - especially over the longer term - are yet to be answered (Hall 2012). The first law of thermodynamics and evidence from various types of studies over the past 50 years, including randomised controlled trials (RCTs), support the view that weight loss occurs when the amount of kilojoules consumed during eating and drinking is less than the amount of kilojoules expended over weeks or months (ACC/AHA 2013 Full Report; Hall 2011; Hall 2012; Hall 2015; Jensen 2014). Thus, a plausible mechanism whereby low-carbohydrate diets enable weight loss is by achieving a sustained energy deficit over time even when advice to explicitly restrict energy intake is not provided. When people eliminate and restrict carbohydrate-rich foods, they are more likely to reduce energy intake because they eat less food

(Brehm 2003; Sondike 2003). Related mechanisms reported in the literature include a reduction in appetite with low-carbohydrate diets, possibly related to the increased intake of fat and production of ketones (Boden 2005; Nordmann 2006; Westman 2007). Since total energy intake is known to drive changes in body weight, its role must be considered when examining the effect on any diet on weight changes.

Some literature indicates that certain macronutrients may have metabolic advantages over others, more specifically that lower carbohydrate intake is more effective for weight loss, independent of energy intake (Atkins 2011; Westman 2007). However, it has been proposed that when proportions of macronutrients in the diet are changed, rapid physiological adaptations occur that aim to match metabolic fuel selection to the diet. Changes in body composition and energy expenditure may be minimised by these adaptations. In this scenario, in the shorter term, all reduced energy diets would have a similar effect on loss of body fat (Hall 2011; Noakes 2006; Tay 2008).

Literature on low-carbohydrate diets also suggest that the reduced insulin secretion resulting from a low-carbohydrate diet causes greater release of adipose tissue free fatty acids, fat oxidation and energy expenditure, and increased loss of body fat compared to restricting fat intake (Ludwig 2014; Taubes 2007; Westman 2007). However, a study in 19 obese adults confined to a metabolic ward demonstrated that an equal kilojoule-selective reduction in dietary fat resulted in no changes in insulin secretion, fat oxidation or energy expenditure and a greater net fat loss when compared to restricting carbohydrates by the same amount, which resulted in decreased insulin secretion, increased fat oxidation and decreased energy expenditure (Hall 2015).

According to recent clinical guidelines for obesity, a high-quality systematic review, a scientific report to inform dietary guidelines and a recent six-month randomised controlled feeding trial, a number of different diets may lead to weight loss over the short term if they achieve a sustained energy deficit, but some of these diets may be more advantageous than others for maintaining longer-term cardiovascular and metabolic health (DGAC 2015; Jensen 2014; Johnston 2014; Wan 2017). There is evidence that weight loss of 5% and more, or BMI reduction of at least 5%, may result in clinically meaningful improvements in cardio metabolic health following dietary regimens (Brown 2016; Truby 2006; Wald 2012; Wing 2010).

Adherence and weight maintenance

Poor dietary adherence has been regarded as one of the reasons popular and traditional dieting strategies are unsuccessful, and it is well known that adherence to nutrition counselling by study participants varies widely. Evidence from quality RCTs, systematic reviews and other study designs suggest that adherence to diets is a primary driver of weight-loss success, regardless of the macronutrient composition, and may explain a considerable part of whether dieters are able to achieve energy deficit for weight loss (Alhassan 2008; Dansinger 2005; Hall 2011; Johnston 2014; Sacks 2009). Dietary intake is difficult to measure accurately, and fidelity of application of dietary assessment methods varies widely across studies (Shim 2014), which may introduce a lot of variation into the assessment of adherence. Consequently, data on adherence to assigned diets are often lacking in weight-loss trials. Also, keeping the weight off once lost is also a considerable challenge in treating

obesity, with most people tending to relapse (Dietz 2015). Indeed, a systematic review including 56 RCTs reported that dieting to lose weight is most often over weeks, months or years, and it is challenging for most people to maintain the weight lost over the long term (Collins 2013). Thus, ease of adherence to weight-reducing diets is a key factor to consider. It is also necessary to consider the time-dependant nature of the relationship between diet and weight change when examining the effect of diets on weight change. Trials typically have different periods of follow-up, and different frequencies or intervals of study contacts and measurement. Tay 2015 indicated that changes sustained over a 12-month period reflects durability of effects over the long term.

Why it is important to do this review

The public spends considerable amounts of money and time on trying to diet, on books about diet, and on products and foods to enhance weight loss. It is therefore important to examine scientific evidence behind the claims made.

Some advocates claim low-carbohydrate diets decrease cardiovascular disease and diabetes risk profiles: reducing triglycerides, increasing high-density lipoprotein (HDL) cholesterol and improving glycaemic control over one year (Stern 2004); improving triglycerides, HDL cholesterol and glycaemic control over four years (Wing 2010); and improving aortic stiffness over four weeks (Syed-Abdul 2018). However, the diets are not without potential side effects. These include gastrointestinal disturbances, such as constipation, flatulence, indigestion or diarrhoea over the short term (Bhardwaj 2017; Brinkworth 2009a; Saslow 2014); and increasing low-density lipoprotein (LDL) cholesterol and non-HDL cholesterol over 12 months (Brinkworth 2009b; Wan 2017). Some participants report mood disturbance and impaired ability to concentrate (Brinkworth 2009c; Halyburton 2007). Other side effects of low-carbohydrate diets include lack of appetite, bad breath, headaches, muscle cramps, general weakness and hair loss (Foster 2010; Rio 2001; Yancy 2004).

A prospective cohort study and meta-analysis that combined 25-year follow-up of the Atherosclerosis Risk in Community (ARIC) data (USA) and seven other cohort studies (USA, Europe, Asia and multinational) assessed the association between carbohydrate intake and mortality (Seidelmann 2018). Findings indicated that both high- and low-carbohydrate diets increased mortality, with the lowest risk observed among those who consumed a diet containing 50% to 55% carbohydrates. The low-carbohydrate dietary patterns that favoured animal fat and protein sources were associated with higher mortality, while those that favoured plant-based foods were associated with lower mortality. Additionally, diets very high in animal source foods could pose a significant threat to environmental sustainability (Sabate 2014; Soret 2014).

The debate on effective and safe diets for treating obesity continues. Many trials and systematic reviews involving obese people (with and without comorbidities), of varying methodological quality, have assessed the effects of low-carbohydrate diets on weight and other risk factors. A number of these studies show little or no clinically important difference in weight loss of up to two years' follow-up (Chawla 2020; Dong 2020; Van Zuuren 2018). A systematic review of eight RCTs found that improvements in psychosocial outcomes occur in participants on short- and longer-term weight-loss programmes, regardless of the macronutrient composition of the diet (Ghoch 2016). However,

low-carbohydrate weight-reducing diets continue to be widely promoted, marketed and commercialised as being more effective for weight loss, and healthier, than weight-reducing diets that have 'balanced' or macronutrient compositions in line with current global dietary recommendations. Healthcare officials argue that very restrictive carbohydrate diets do not promote behaviour changes that foster varied, nutrient- and fibre-rich dietary patterns (USDA 2014), known to reduce risks of cardiovascular disease, hypertension, T2DM and certain cancers. Extreme restriction or excess of macronutrients, as advised with very low-carbohydrate diets, instead promote a way of eating that is likely to result in an imbalance of macronutrient intake, suboptimal micronutrient intake and increased disease risk over time.

Previously, we took stock of existing systematic reviews on low-carbohydrate diets for adults wanting to lose weight. We found 50 existing reviews (last search date: 3 March 2014), with a number of shortcomings as reported in Naude 2014. This exercise helped inform the protocol for our earlier systematic review and meta-analysis of RCTs (Naude 2014). This Cochrane Review will be a fresh edition to Naude 2014, by taking into account new eligible trials, and comments and criticisms generated by the earlier work.

OBJECTIVES

To compare the effects of low-carbohydrate weight-reducing diets to weight-reducing diets with balanced ranges of carbohydrates, in relation to changes in weight and cardiovascular risk, in overweight and obese adults without T2DM (comparisons 1 and 2) and with T2DM (comparisons 3 and 4)

METHODS

Criteria for considering studies for this review

Types of studies

As per our protocol (Naude 2019), we included parallel-arm individual- and cluster-randomised controlled trials (RCTs) that had an active weight-reducing intervention phase of at least 12 weeks. According to Jensen 2014, obese individuals on a moderately restricted energy intake can potentially lose between six and eight kilograms, or five to ten per cent of initial body weight (clinically meaningful) over a six-month period. From this, we inferred that it would be plausible to lose five per cent of initial weight over a three-month period. According to the UK National Institute for Health and Care Excellence (NICE), 12 weeks is the standard length for most commissioned dietary interventions (Ahern 2017; NICE 2014). Follow-up of participants after the intervention ended could be of any duration.

We excluded quasi-randomised trials (that is, trials that used an inadequate method of randomisation, such as alternation or date of birth). We included cross-over trials where the first phase was 12 weeks or longer, and where data for the first phase per group were available. We excluded cross-over trials not meeting these criteria due to the possible period and carry-over effects that would arise with the eligible dietary interventions, condition (overweight and obesity) and outcomes in this review, with these not being easily reversible as required for a valid cross-over design (Younge 2015).

We only included studies with a weight-maintenance phase if the preceding weight-reducing phase was for 12 weeks or longer,

and relevant data from this phase were available. We separated analyses for weight-reducing and weight-maintenance phases.

Types of participants

We included adults (18 years and older) who were overweight or living with obesity (as defined by trial authors), with or without T2DM, and with or without cardiovascular conditions or risk factors such as hypertension or dyslipidaemia (as defined by trial authors).

We excluded studies where pregnant and lactating women were included, as well as studies in people with specific medical conditions such as bipolar disorder, polycystic ovary syndrome, chronic renal disease, and so on.

We included studies involving a subset of eligible participants (for example, adults and children, as defined by trial authors) if results were reported separately for the eligible subset (for example, those ≥ 18 years). If not, we only included such studies if 80% or more of the baseline sample were eligible for our review (for example, aged ≥ 18 years). We excluded data from such studies in sensitivity analyses to test the robustness of the primary meta-analyses.

Types of interventions

Treatment diet

We included RCTs investigating low-carbohydrate weight-reducing diets where the diets were explicitly implemented for the primary purpose of reducing weight, with or without explicit advice to restrict total energy intake.

Control diet

We included RCTs where the control diets had a carbohydrate content within the balanced range of 45% to 65% of total energy, and where the diets were explicitly implemented for the primary purpose of reducing weight, with or without advice to restrict total energy intake.

We included studies where diets were implemented by provision of advice, food or both. However, we excluded studies with the following.

- Treatment diet had carbohydrate content 45% or more of total energy or more than 150 g per day.
- Treatment and control diets were different in some other respect that may influence the predefined outcomes, except for total energy intake.
- Treatment or control diets were not adequately defined (and could not be obtained from study authors) or where the control diet was 'no dietary intervention'.
- Diets were combined with any other co-interventions (e.g. exercise, pharmacological, surgical) where these differed by group.
- Dietary interventions had an exclusive focus on energy restriction (i.e. no macronutrient manipulation was explicitly instituted).
- Interventions focused solely on specific foods (e.g. oats), food groups (e.g. dairy) or food components (e.g. plant sterols), or where meal replacements or supplements were part of the diets and were different in the diets being compared.
- Participants were selected based on a possible prognostic variable (for example, genotype).

Types of outcome measures

We did not exclude studies on the basis of outcomes measured. However, we did exclude studies measuring only immediate meal responses (e.g. postprandial changes in blood sugar) and not longer-term physiological responses to diet.

Primary outcomes

- Change in body weight (kg) from baseline
- Number of participants per group with weight loss of at least 5% from baseline

We assessed the primary outcomes at short-term (3 months to < 12 months) and long-term (≥ 12 months) follow-up.

Secondary outcomes

Clinical

- Change in body mass index (BMI; kg/m²) from baseline
- Number of participants per group with reduction in BMI of at least 5% from baseline

We assessed the above clinical outcomes at short-term (three months to < 12 months) and long-term (≥ 12 months) follow-up.

- Change in diastolic blood pressure (mmHg)
- Change in systolic blood pressure (mmHg)
- All-cause mortality
- Cardiovascular mortality
- Non-fatal myocardial infarction
- Non-fatal stroke
- Diagnosis of T2DM (as reported by study authors)

We assessed these clinical outcomes at long-term (≥ 12 months) follow-up only.

Laboratory

- Change in glycosylated haemoglobin (HbA1c) (%)
- Change in serum low-density lipoprotein (LDL) cholesterol (mmol/L)
- Change in serum high-density lipoprotein (HDL) cholesterol (mmol/L)
- Change in serum non-HDL cholesterol (mmol/L)
- Change in serum total cholesterol (mmol/L)
- Change in serum triglycerides (mmol/L)

We assessed these laboratory outcomes at long-term (≥ 12 months) follow-up only.

Participant-reported adverse effects

Participant-reported adverse effects, specifically in regard to lack of appetite, bad breath, weakness, headaches, gastrointestinal problems (constipation, diarrhoea, flatulence, indigestion) and psychosocial problems (mood disturbances) at any time point, limited to those described in included studies. We regarded constipation as a patient-important outcome since it is frequently reported by people following low-carbohydrate diets.

Search methods for identification of studies

We used a comprehensive search strategy aiming to identify all eligible studies regardless of language or publication status.

Electronic searches

We identified RCTs through systematic searches of the following bibliographic databases:

- MEDLINE (PubMed, from 1946 to 25 June 2021)
- Cochrane Central Register of Controlled Trials (CENTRAL; 2021, Issue 6), in the Cochrane Library
- Embase (Ovid, from 1947 to 28 June 2021)
- Web of Science Core Collection with Indexes SCI-Expanded, SSCI, CPCI-S (Clarivate Analytics, from 1970 to 25 June 2021)

We also on 25 June 2021 searched ClinicalTrials.gov (www.ClinicalTrials.gov) and the WHO International Clinical Trials Registry Platform (ICTRP) for ongoing and unpublished trials (apps.who.int/trialsearch).

We first designed the search strategy for MEDLINE (PubMed) and then adapted it for use in the other sources (Appendix 1).

We did not do a separate search for adverse effects of interventions; we only considered adverse effects reported in included studies.

Searching other resources

We checked reference lists of all included studies and relevant systematic reviews identified for additional references to trials. We set out to examine any relevant retraction statements and errata for included studies; however, we did not come across any.

Data collection and analysis

Selection of studies

We imported all de-duplicated search records into [Covidence](#). Two review authors independently screened the titles and abstracts of these records to identify all potential eligible studies. Discrepancies in first-line screening choices were resolved by discussion among at least two review authors. We retrieved the full-text report for each record that the screeners considered potentially eligible, and two review authors (CN, KN, AS, AB) independently screened all full texts, identifying studies for inclusion, and identifying and recording reasons for exclusion of the ineligible studies. We resolved any disagreement through discussion or, if required, consultation with a third review author (TY, JV). We identified and excluded duplicates and collated multiple reports of the same study so that each study, rather than each report, was the unit of interest in the review. We recorded the selection process in sufficient detail to complete a PRISMA flow diagram ([Moher 2009](#)), and 'Characteristics of excluded studies' table. Studies where full reports (published or unpublished) were not available (e.g. conference abstracts), or where there was unclear or missing information (that could not be obtained from study authors) such that we could not ascertain study eligibility, were placed, with a reason, in the 'Characteristics of studies awaiting classification' table.

Data extraction and management

To extract study characteristics and outcome data, we created a data collection form in DistillerSR ([DistillerSR](#)), and piloted it on two included studies. Data from each included study were extracted independently by two review authors (AB, KN, AS, CN). We contacted the study authors when reported information was unclear or contradictory, or when important data were missing. It was not necessary to seek translations. We extracted the following:

- Methods: authors' contact details, type of record (e.g. journal article, thesis), study design, study population, study dates, total duration of the intervention and follow-up duration after the intervention where relevant, details of 'run-in' periods where relevant, number of study centres and location, study setting, method of recruitment, number of study arms, description of eligible study arms, outcome used for sample size calculation, unit of allocation, number randomised per study arm (for individually-randomised trials), number of clusters and number of participants per cluster who consented (for cluster-randomised trials), number of withdrawals and those lost to follow-up, number completed and analysed, other relevant notes on the methods.
- Participants: inclusion and exclusion criteria, age, gender (number of male and female participants per group), baseline body weight status, other baseline cardiovascular disease risk factors and potential confounders, any group differences.
- Interventions: treatment diet, control diet, implementation or delivery of diets, dietary intake assessments (e.g. what, how frequent, by whom), concomitant interventions.
- Outcomes: primary and secondary outcomes specified and collected at relevant time points, data on adherence to the interventions, and whether primary study authors analysed results separately according to gender.
- Notes: study funding, conflicts of interest declarations of study authors, and other relevant notes.

For outcomes, we extracted change data (i.e. change from baseline to outcome assessment per group) where possible, with relevant data on variance for treatment and control arms and numbers of participants per arm at that time point. Where change data were not available, we extracted and used data at study end (i.e. end values), or other relevant time points, along with variance and number of participants per arm at that time point.

Where possible, we converted variables to comparable units to allow pooling of data, if appropriate. [Calleja-Fernández 2012](#) stratified by homeostatic model assessment (insulin resistant (IR) and insulin sensitive (IS)) before randomisation. We combined IR and IS group data using Cochrane methods to combine subgroups ([Higgins 2021](#)). [Saslow 2017a](#) reported appetite change as hunger change scores using means and Cohen's d values for each diet group. We converted Cohen's d values to standard deviations (SD) using the formula $SD = \text{mean}/\text{Cohen's } d$.

We stratified included trials into those in participants without T2DM (comparisons 1 and 2) and those in participants with T2DM (comparisons 3 and 4).

We resolved disagreements by consensus or by involving a third review author (MC, TY, JV). We exported data from DistillerSR and imported it into the latest version of Review Manager Web ([RevMan Web 2020](#)) via Microsoft Excel. We completed the 'Characteristics

of included studies' table for all included studies. We used key items from the TIDieR checklist (Hoffman 2014) to aid description, interpretation and discussion of the results. Brief details of ongoing studies are reported in the 'Characteristics of ongoing studies' table, and these studies will be considered for inclusion in a future update of the review.

Assessment of risk of bias in included studies

Three reviewers (CN, AB and AS) assessed risk of bias for each study using the Cochrane Risk of Bias 2 tool (RoB2) for randomised controlled trials (Sterne 2019). This tool was used to assess the effect of the assignment to the intervention, for the following domains:

- bias arising from the randomisation process;
- bias due to deviations from intended interventions;
- bias due to missing outcome data;
- bias in measurement of the outcome;
- bias in selection of the reported result.

We did not have to carry out the planned assessments of risk of bias for cross-over and cluster-randomised controlled trials, as none of the eligible trials had these designs.

We judged each domain as either 'low risk of bias', 'some concerns' or 'high risk of bias' for the following outcomes reported in the summary of findings tables:

- change in body weight (kg) measured from baseline to between three and < 12 months;
- change in body weight (kg) measured from baseline to ≥ 12 months;
- number of participants per group with weight loss of at least 5% measured from baseline to ≥ 12 months;
- cardiovascular mortality measured from baseline to ≥ 12 months;
- change in diastolic blood pressure (mmHg) measured from baseline to ≥ 12 months;
- change in HbA1c (%) (for comparisons in participants with T2DM) measured from baseline to ≥ 12 months;
- change in serum LDL cholesterol (mmol/L) measured from baseline to ≥ 12 months;
- participant-reported constipation at any time point from baseline to three and < 12 months.

Overall, per included study, we made judgements according to the following criteria:

- low risk of bias: when all domains were at low risk;
- some concerns: when one or more domains had some concerns, but none were at a high risk of bias;
- high risk of bias: when one or more domains were at high risk of bias, or multiple domains had some concerns to the extent that these reduced confidence in the results.

We resolved any disagreements by discussion or by involving another review author (MC or AS).

Measures of treatment effect

For dichotomous data, we used the number of events as the numerator and the total sample size per outcome as the denominator in each relevant comparison group and computed the risk ratio (RR) (available case data). For continuous data, we reported results per outcome as the difference in the mean change (and, if not available, the difference in end values) between the treatment and control groups, and computed the mean difference (MD) (available case data). We entered data presented as a scale with a consistent direction of effect. We used Review Manager Web to conduct meta-analyses for each outcome, where appropriate, to determine a pooled effect of low-carbohydrate diets compared to balanced-carbohydrate diets. We narratively described skewed data reported as medians and interquartile ranges.

Unit of analysis issues

In the case of multiple intervention groups, we selected one pair of interventions (treatment and control) most relevant to this systematic review question. We did not need to apply the planned approach for unit of analysis issues related to clustering as no cluster-randomised trials were eligible. Where a study reported outcome data for more than one time point within our time point categories (3 months to < 12 months; and ≥ 12 months), we used the longest time point (for example, where results were available at three months and five months, we only used the five-month data).

Dealing with missing data

We contacted study authors or sponsors to clarify key study characteristics and obtain missing numerical outcome data, where needed. Where study authors had not reported all relevant statistics per outcome (for example, sample size, mean change and standard deviation of change per group), we calculated or estimated the required data from other reported statistics using formulas specified in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011), if possible. Where we could not calculate or estimate these statistics with reasonable confidence, we contacted the study authors by email. When we did not receive a response, we did not impute the missing values, but reported the available results narratively or in a table, as appropriate. For interventions in which there was substantial attrition (15% or more for at least one of the groups) of study participants, we reported the attrition rate. We also performed sensitivity analyses excluding studies with some concerns or a high risk of bias for the missing outcome data domain in RoB 2.

Assessment of heterogeneity

We examined heterogeneity per outcome firstly by visual inspection of the forest plots (i.e. we looked at physical overlap of confidence intervals across the included studies). Secondly, we assessed statistical heterogeneity among the intervention effects across the included studies in each meta-analysis as follows:

- Chi² test for heterogeneity
- I² statistic to quantify heterogeneity
- Tau² statistic to measure the extent of heterogeneity

In our meta-analyses, we considered substantial heterogeneity as an I² statistic value of greater than 50% and either a Chi² test of less than 0.1 or Tau² statistic greater than 0. In meta-analyses with substantial heterogeneity, we performed prespecified subgroup

analyses on the outcomes in the summary of findings tables. Where we identified unexplained substantial heterogeneity, we did not pool results into an overall effect estimate but rather presented the individual effect sizes per study for the specific outcome.

Assessment of reporting biases

Where data per comparison and outcome allowed us to pool more than 10 studies, we explored the possibility of small study biases for the primary outcomes using funnel plots. In the case of asymmetry, we considered various explanations such as publication bias, poor study design and the effect of study size.

Data synthesis

We used a random-effects model for meta-analyses since we anticipated heterogeneity between included studies due to variations in the composition of weight-loss diets, adherence to diets, intervention duration and dietary assessment methodology. For dichotomous outcomes, we used the Mantel-Haenszel method, unless the number of events were not available but estimates of effect measure and their standard errors were, in which case we used the inverse variance method. For continuous outcomes, we used the inverse variance method.

We analysed trials in overweight and obese participants without T2DM following diets with a weight-reducing phase only (comparison 1), or a weight-reducing phase followed by a weight-maintenance phase (comparison 2); as well as overweight and obese participants with T2DM following diets with a weight-reducing phase only (comparison 3), or a weight-reducing phase followed by a weight-maintenance phase (comparison 4). These analyses were done separately, where possible, as the presence of diabetes is likely to influence the effects of the diets. When not explicitly stated, we regarded weight-maintenance phases as periods where initial diet prescriptions or advice changed to indicate less focus on active weight reduction, for example, changes in energy prescriptions or no restrictions on carbohydrate intake.

We analysed outcome data at the time point ≥ 12 months, because it captures sustainability of effects on weight loss, clinical, as well as laboratory outcomes. However, for the weight and BMI outcomes, we also analysed data at the time point three months to < 12 months, as many people going on weight-loss diets are especially interested to know how fast they would be losing weight, and experienced weight loss over the short term also serves as motivation to keep going longer term.

We preferentially extracted and used data from the intention-to-treat (ITT) analyses of trials (as reported by trial authors) in all our meta-analyses. By ITT, we mean that randomised participants were analysed according to the group to which they were randomised; however, if there were missing data we did not perform any imputations.

Subgroup analysis and investigation of heterogeneity

Where data allowed, we carried out the following subgroup analyses for the outcomes in the summary of findings tables, to explore substantial heterogeneity and the stability of findings in different study subgroups, as follows.

- By extent of carbohydrate restriction (i.e. very low-carbohydrate or ketogenic diets: carbohydrate prescription of ≤ 50 g per day or

$< 10\%$ of total daily energy intake from a nominal 8400 kilojoule (approximately 2000 kilocalories) diet; and non-ketogenic low-carbohydrate diets: > 50 g to 150 g per day or $< 45\%$ of total energy intake)

- By similarity of total energy prescription (i.e. studies with substantial differences in daily total energy prescription (> 500 kilojoules or approximately 120 kilocalories) in treatment and control groups, for example, ad libitum energy prescription in the treatment diet and restricted energy prescription in the control diet, studies with similar energy prescription or similar approach used to restrict energy intake in treatment and control groups, studies with no energy prescription reported or unrestricted energy intake prescribed in both treatment and control groups)
- By diagnosed cardiovascular event or disease (i.e. studies in people with no events or disease, studies in people with events or disease, and studies in people with and without events or disease)
- By gender

Sensitivity analysis

Where data allowed, we carried out sensitivity analyses for primary outcomes, assessing the effect of:

- overall low risk and 'some concerns' of bias (i.e. we first pooled all relevant studies per outcome, and then pooled only studies with overall low risk and 'some concerns' of bias);
- attrition bias (i.e. we first pooled all relevant studies per outcome, and then pooled only studies at low risk of bias for the missing outcome data domain);
- studies including only a subset of eligible participants for this review (i.e. we first pooled all relevant studies per outcome, and then pooled only studies that included only participants eligible for inclusion in this review);
- clustering (i.e. we first pooled all relevant studies per outcome, and then pooled only studies that randomised individual participants); and
- source of funding (i.e. we first pooled studies with all funding sources, and then pooled only studies without diet/food industry funding).

Summary of findings and assessment of the certainty of the evidence

Based on the methods described in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2011), we prepared four summary of findings tables, one for each comparison in participants without and with T2DM. In these tables, we included change in body weight (kg) measured from baseline to between three and < 12 months, and the following outcomes measured from baseline to ≥ 12 months: change in body weight (kg); number of participants per group with weight loss of at least 5%; cardiovascular mortality; change in diastolic blood pressure (mmHg); change in HbA1c (%) (for comparisons 3 and 4 in participants with T2DM); change in serum LDL cholesterol (mmol/L), as well as participant-reported constipation at 3 to < 12 months. We used the GRADE approach to rank the certainty of the evidence as it related to the studies that contributed data to the meta-analyses for the prespecified outcomes, using GRADEpro GDT software (www.grade.org). The GRADE tool includes five considerations (study limitations, inconsistencies of

results, imprecision, indirectness and publication bias) to assess the certainty of the evidence from RCTs.

We justified all decisions to downgrade the quality of evidence using footnotes, and made comments to aid readers' understanding where necessary.

Three review authors (CN, AS, AB) made judgements about evidence certainty, with disagreements resolved by discussion, and involving a third review author where needed.

We extracted study data, formatted our comparisons in data tables and prepared a summary of findings table for each of the four comparisons before writing the results and conclusions of our review.

RESULTS

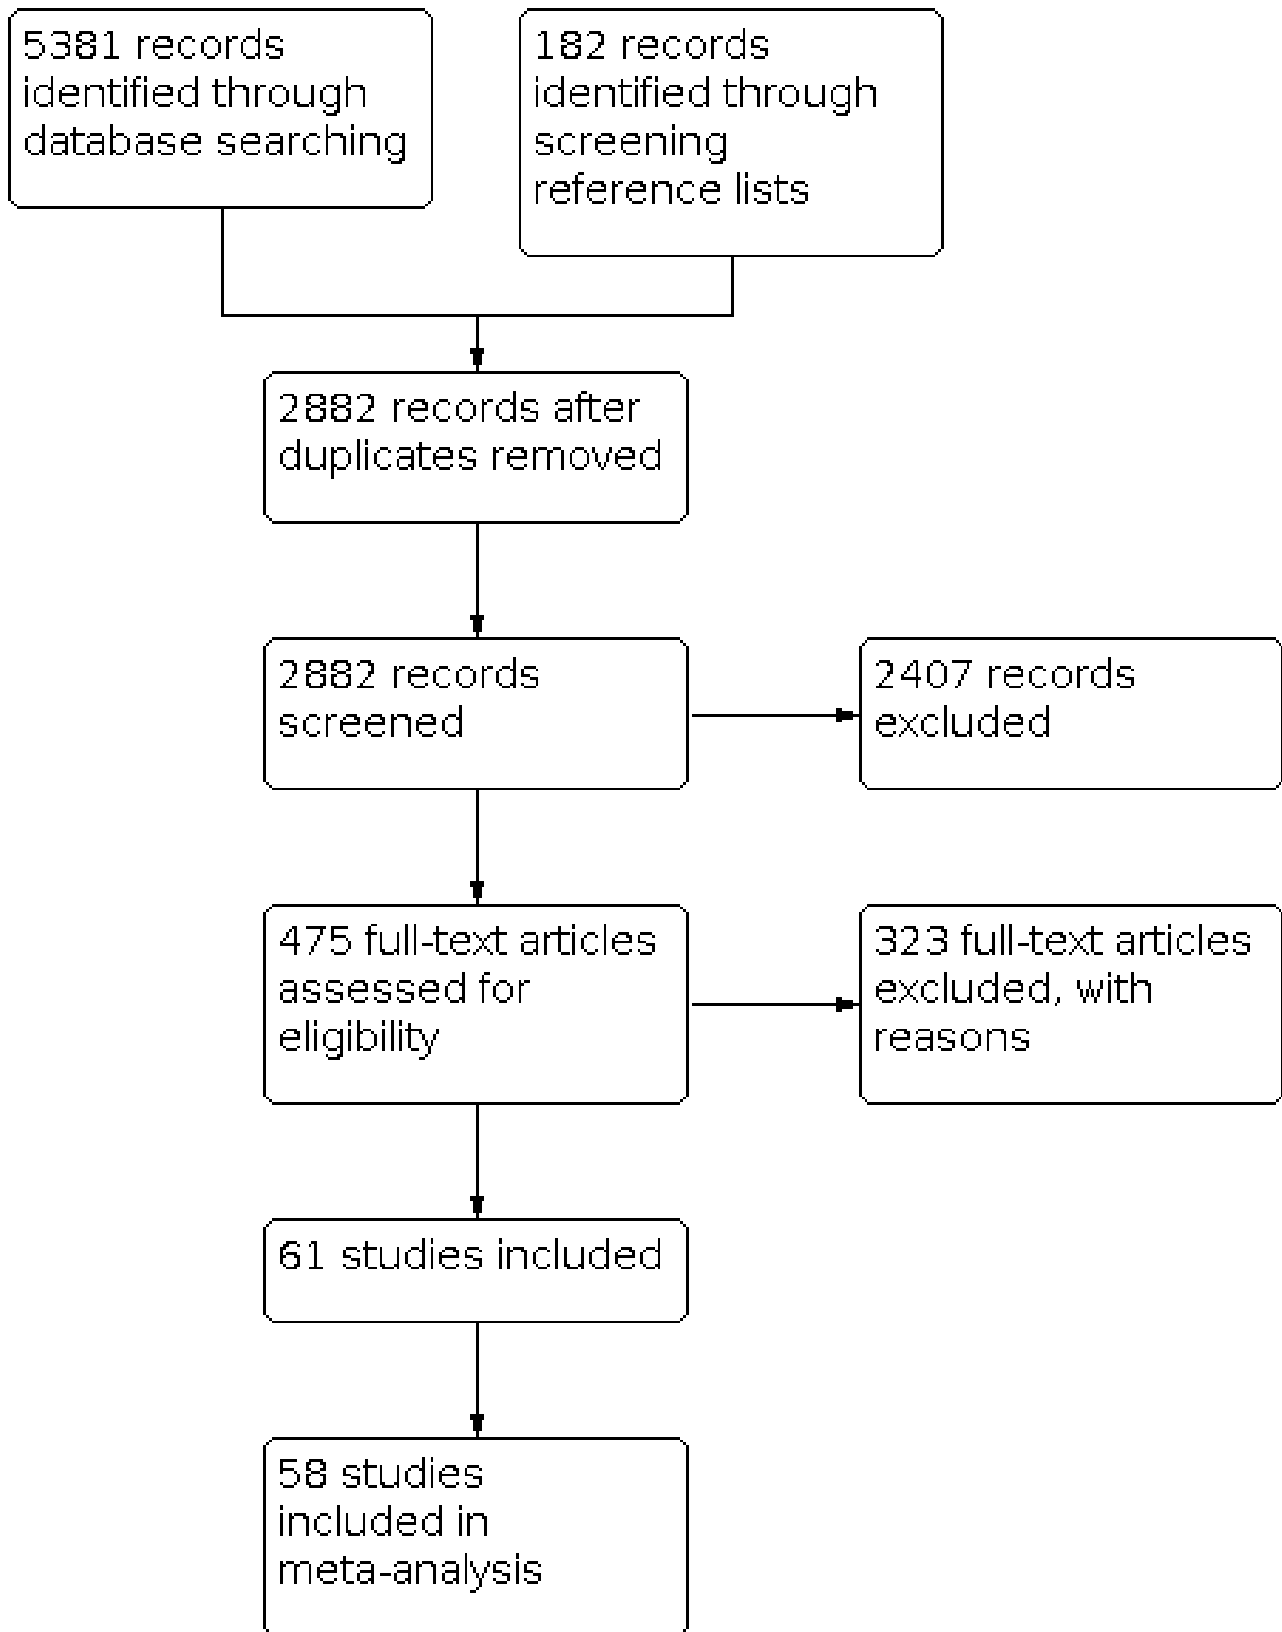

Description of studies

See: [Characteristics of included studies](#); [Characteristics of excluded studies](#); [Characteristics of ongoing studies](#); [Characteristics of studies awaiting classification](#).

Results of the search

Our electronic and manual searches yielded 5563 references, which included screening the reference lists of included trials and existing systematic reviews, with 2882 remaining after duplicate removal. We screened the titles and abstracts of these records and identified 475 as potentially eligible and obtained their full texts. We included 61 trials from 113 references ([Figure 1](#)), of which three did not provide data that could be used in the quantitative syntheses (meta-analyses) ([Foster 2003](#); [Pittas 2005](#); [Racette 1995](#)).

Figure 1.

Included studies

Study locations and participants

We included 61 parallel-arm individual RCTs that randomised 6925 participants to either low-carbohydrate or balanced-carbohydrate weight-reducing diets, and were published between 1978 and 2021. All trials were done in high-income countries, except for one in China (Liu 2013); with 26 in the USA (Aude 2004; Bales 2017; Bazzano 2014; Brehm 2003; Brehm 2005; Cornier 2005; Ebbeling 2007; Evangelista 2021; Foraker 2014; Foster 2003; Foster 2010; Gardner 2007; Kitabchi 2013; Landers 2002; Lasker 2008; Layman 2005; Layman 2009; Pittas 2005; Racette 1995; Ruth 2013; Sacks 2009; Samaha 2003; Saslow 2017a; Stentz 2016; Volek 2009; Westman 2008); 14 in Australia (Benassi-Evans 2009; Farnsworth 2003; Griffin 2013; Jesudason 2013; Keogh 2007; Larsen 2011; Lim 2010; Parr 2016; Pedersen 2014; Tay 2008; Tay 2014; Watson 2016; Wycherley 2010; Wycherley 2012); five in Spain (Calleja-Fernández 2012; Goni 2018; Juanola-Falgarona 2014; Marco-Benedi 2019; Mateo-Gallego 2017); three in the UK (Dyson 2007; Hockaday 1978; Lean 1997), two in Sweden (Guldbrand 2012; Mellberg 2014), Norway (Klemsdal 2010; Veum 2017), Germany (Frisch 2009; Haufe 2013) and Japan (Sato 2017; Yamada 2014); and one each in Canada (Josse 2011), Israel (Elhayany 2010), Singapore (Ooi 2021) and New Zealand (Krebs 2012). The large majority of trials were undertaken in outpatient clinics, medical centres and research centres (50/61 trials), with the remaining 11 not reporting a specific study setting. See the Characteristics of included studies for additional details per study.

Type 2 diabetes mellitus status of participants

We stratified trials into those in participants without T2DM (comparisons 1 and 2) and those in participants with T2DM (comparisons 3 and 4), and also separated findings where people implemented only an active weight-reducing phase of the diets, from findings where people implemented a weight-reducing phase followed by a weight-maintenance phase of the diets, as follows:

- comparison 1: trials in participants without T2DM including only weight-reducing phases of diets;
- comparison 2: trials in participants without T2DM including weight-reducing phases of diets followed by weight-maintenance phases;
- comparison 3: trials in participants with T2DM including only weight-reducing phases of diets;
- comparison 4: trials in participants with T2DM including weight-reducing phases of diets followed by weight-maintenance phases.

We included 45/61 trials (n = 5118 randomised) in the two comparisons in participants without T2DM (comparisons 1 and 2). Of these, 36 trials explicitly excluded participants with T2DM. For the remaining trials with mixed participants or where this was unclear (n = 9), the participants' baseline characteristics (e.g. HbA1c, fasting insulin, use of diabetes medication) were not indicative of diabetes (Bales 2017; Foraker 2014; Liu 2013; Marco-Benedi 2019), more than 90% of the sample did not have T2DM (Aude 2004; Frisch 2009), participants with unstable metabolic disease were excluded (Jesudason 2013), or no relevant information was reported or could be obtained (Layman 2005; Layman 2009).

We included 14/61 trials (n = 1604 participants randomised) in the two comparisons in participants with T2DM (comparisons 3 and 4). Thirteen of these trials were conducted in participants with diagnosed T2DM (Elhayany 2010; Evangelista 2021; Guldbrand 2012; Hockaday 1978; Krebs 2012; Larsen 2011; Pedersen 2014; Sato 2017; Tay 2014; Watson 2016; Westman 2008; Wycherley 2010; Yamada 2014). The other trial had mixed participants with eligibility criteria being diabetes or prediabetes and more than 70% of participants were on diabetes medication at baseline (Saslow 2017a).

Two trials (n = 158 participants randomised) were conducted in participants without and with T2DM and reported data separately for all (Dyson 2007), or some outcomes (Samaha 2003), which we included in the appropriate comparisons, where possible. For the descriptions of participants, treatment and control diets that follow in this section, these two trials (Dyson 2007; Samaha 2003), are included with both strata of participants (without and with T2DM).

Participants without T2DM: weight-reducing phase only (comparison 1) and weight-reducing phase followed by a weight-maintenance phase (comparison 2)

Sample size: The total numbers of participants randomised to the treatment and control diet arms ranged widely across these trials. The smallest trial randomised 20 participants (Racette 1995). Other small trials with 40 or fewer participants randomised included Cornier 2005; Dyson 2007; Kitabchi 2013 and Layman 2005. The largest trial in participants without T2DM was Sacks 2009 (n = 405 randomised), with other trials including > 150 participants being Foster 2010; Frisch 2009; Haufe 2013; Jesudason 2013; and Klemsdal 2010.

Gender and age: In three of these trials, only men were eligible (Benassi-Evans 2009; Veum 2017; Wycherley 2012), in 16 only women (Bales 2017; Brehm 2003; Brehm 2005; Cornier 2005; Foraker 2014; Gardner 2007; Griffin 2013; Jesudason 2013; Josse 2011; Kitabchi 2013; Layman 2005; Lean 1997; Liu 2013; Mateo-Gallego 2017; Mellberg 2014; Racette 1995), and in the rest, both men and women were eligible. Mean baseline age of participants across these trials was 45 years (range: 22 to 62 years).

Weight status: At baseline, mean body weight and BMI of participants without T2DM was 93.9 kg (range: 65 to 132 kg) and 33.6 kg/m² (range: 30 to 43 kg/m²), respectively.

Cardiovascular health and risk factors: The majority of these trials included participants without cardiovascular conditions, risk factors or events at baseline (n = 30), one included participants with and without these (Aude 2004), and for the remaining trials this was unclear (Bales 2017; Calleja-Fernández 2012; Dyson 2007; Foraker 2014; Juanola-Falgarona 2014; Keogh 2007; Kitabchi 2013; Lasker 2008; Layman 2005; Marco-Benedi 2019; Mateo-Gallego 2017; Samaha 2003; Stentz 2016; Veum 2017; Volek 2009). Mean baseline LDL cholesterol concentration across these trials was 3.28 mmol/L (range: 2.58 to 4.47 mmol/L) and mean baseline DBP was 79 mmHg (range: 62 to 92 mmHg).

Participants with T2DM: weight-reducing phase only (comparison 3) and weight-reducing phase followed by a weight-maintenance phase (comparison 4)

Sample size: The smallest trial in participants with T2DM randomised a total of 24 participants to the treatment and control diet arms (Yamada 2014), with other small trials (40

or fewer participants randomised) being [Dyson 2007](#); [Saslow 2017a](#); and [Wycherley 2010](#). The largest trial in participants with T2DM randomised 419 participants ([Krebs 2012](#)). Other trials including more than 130 participants were [Elhayany 2010](#); [Samaha 2003](#); and [Tay 2014](#).

Gender and age: In all trials in participants with T2DM, both men and women were eligible for inclusion. Mean age of participants at baseline was 57 years (range: 50 to 65 years).

Weight status: Mean baseline body weight of participants across these trials was 96.7 kg (range: 67 to 132 kg) and mean BMI was 34.5 kg/m² (range 25 to 42.9 kg/m²).

HbA1c: Mean baseline HbA1c of participants across these trials was 7.64% (range: 6.6% to 8.8%).

Cardiovascular health: Six of these trials included participants without cardiovascular conditions, risk factors or events at baseline ([Hockaday 1978](#); [Krebs 2012](#); [Larsen 2011](#); [Tay 2014](#); [Watson 2016](#); [Wycherley 2010](#)), one included participants with heart failure ([Evangelista 2021](#)), and, for the rest of the trials, this was unclear. Mean baseline LDL cholesterol across these trials was 2.63 mmol/L (range: 1.7 to 3.2 mmol/L) and mean baseline DBP was 78 mmHg (range: 70 to 84 mmHg).

Treatment and control diets

Trials in participants without T2DM: weight-reducing phase only (comparison 1) and weight-reducing phase followed by a weight-maintenance phase (comparison 2)

Duration: The duration of the weight-reducing phases of diets tested in these trials ranged from 12 weeks to two years, as follows: 10 trials for 12 weeks ([Aude 2004](#); [Dyson 2007](#); [Farnsworth 2003](#); [Keogh 2007](#); [Landers 2002](#); [Liu 2013](#); [Racette 1995](#); [Ruth 2013](#); [Veum 2017](#); [Volek 2009](#)), eight trials for 16 weeks ([Brehm 2005](#); [Cornier 2005](#); [Goni 2018](#); [Josse 2011](#); [Lasker 2008](#); [Layman 2005](#); [Ooi 2021](#); [Parr 2016](#)), 12 trials for six months ([Bales 2017](#); [Brehm 2003](#); [Foster 2003](#); [Foster 2010](#); [Haufe 2013](#); [Juanola-Falgarona 2014](#); [Kitabchi 2013](#); [Lean 1997](#); [Marco-Benedi 2019](#); [Mateo-Gallego 2017](#); [Pittas 2005](#); [Stentz 2016](#)), 12 trials for one year ([Bazzano 2014](#); [Benassi-Evans 2009](#); [Calleja-Fernández 2012](#); [Foraker 2014](#); [Frisch 2009](#); [Gardner 2007](#); [Griffin 2013](#); [Klemsdal 2010](#); [Layman 2009](#); [Samaha 2003](#); [Tay 2008](#); [Wycherley 2012](#)), one trial for 15 months ([Lim 2010](#)), one trial for 18 months ([Ebbeling 2007](#)), and three trials for two years ([Jesudason 2013](#); [Mellberg 2014](#); [Sacks 2009](#)). We used only the data from the first six months in two trials with total durations of one year ([Foster 2003](#)) and two years ([Foster 2010](#)) since the treatment diets were ineligible from six months onwards due to the prescribed incremental carbohydrate increases. The results for only the active weight-reducing phases of the diets in participants without T2DM were reported in comparison 1.

Five of these trials also implemented a weight-maintenance phase following the weight-reducing phase for six weeks ([Racette 1995](#)), 40 weeks ([Keogh 2007](#)), 56 weeks ([Farnsworth 2003](#)), a variable time period with an average of 18 months ([Haufe 2013](#)) and 21 months ([Dyson 2007](#)), and these results were reported in comparison 2.

Macronutrient prescription: [Table 1](#) contains the thresholds and ranges used to characterise the macronutrient prescriptions of the treatment and control diets in this review. In [Table 2](#), we used the characterisations in [Table 1](#) to summarise the macronutrient

compositions of the treatment and control diets tested in each trial in participants without T2DM.

The extent of carbohydrate restriction in the treatment diets ranged from very low (≤ 50 g per day or $< 10\%$ of total daily energy intake) ($n = 11$) to low (> 50 g to 150 g per day or $< 45\%$ of total energy intake) ($n = 31$), with five trials examining the effects of treatment diets with incremental increases in carbohydrates from very low to low ([Table 2](#)). Implementation of these incremental increases varied widely across the five trials, with the prescribed time for following the very low-carbohydrate diets ranging from one week to three months. Different prescriptions for incremental increases in carbohydrate intake in the later phases included increases from 10% to 27% of total energy as carbohydrates, by 5 g/day/week, by 10 g weekly, and from 20 g to 50 g per day. As expected, the protein and fat proportions of treatment diets also varied concordantly. The control diets in the majority of trials in participants without T2DM were balanced for carbohydrates, fat and protein ($n = 38$) ([Table 2](#)).

The most common diets compared across the trials in participants without T2DM were low-carbohydrate, balanced-fat and high-protein treatment diets compared to control diets balanced for all three macronutrients ($n = 19$), followed by very low-carbohydrate treatment diets with unspecified fat and protein contents compared to control diets with balanced proportions of carbohydrates, fat and protein ($n = 7$) ([Table 2](#)).

Total energy prescription: In most of these trials, the total energy prescription was similar, or the approach used to restrict energy intake was similar in treatment and control groups ($n = 34$). In nine other trials, the energy prescription was ad libitum in the treatment diets and restricted in the control diets ([Aude 2004](#); [Brehm 2003](#); [Brehm 2005](#); [Foster 2003](#); [Foster 2010](#); [Gardner 2007](#); [Landers 2002](#); [Liu 2013](#); [Samaha 2003](#)). In the remaining trials, no energy prescription was reported, or unrestricted energy intake was prescribed for both treatment and control diets ([Bazzano 2014](#); [Ebbeling 2007](#); [Mellberg 2014](#); [Volek 2009](#)).

Trials in participants with T2DM: weight-reducing phase only (comparison 3) and weight-reducing phase followed by a weight-maintenance phase (comparison 4)

Duration: The duration of the weight-reducing phases of diets tested in these trials ranged from 12 weeks to two years, as follows: four trials for 12 weeks ([Dyson 2007](#); [Evangelista 2021](#); [Larsen 2011](#); [Watson 2016](#)), one trial for 16 weeks ([Wycherley 2010](#)), three trials for six months ([Sato 2017](#); [Westman 2008](#); [Yamada 2014](#)), five trials for one year ([Elhayany 2010](#); [Hockaday 1978](#); [Pedersen 2014](#); [Samaha 2003](#); [Saslow 2017a](#)), and three trials for two years ([Guldbrand 2012](#); [Krebs 2012](#); [Tay 2014](#)). The results for only the active weight-reducing phases of diets in participants with T2DM were reported in comparison 3.

Four of these trials also implemented a weight-maintenance phase following their weight-reducing phase for 12 weeks ([Watson 2016](#)), nine months ([Larsen 2011](#)), 12 months ([Sato 2017](#)), and 21 months ([Dyson 2007](#)), and we reported these results in comparison 4.

Macronutrient prescriptions: [Table 3](#) summarises the macronutrient prescriptions of the treatment and control diets tested in each trial in participants with T2DM using the characterisations in [Table 1](#).

The extent of carbohydrate restriction in the treatment diets ranged from very low (≤ 50 g per day) ($n = 5$) to low (> 50 g to 150 g per day or $< 45\%$ of total energy intake) ($n = 11$). No trials in participants with T2DM tested treatment diets with incremental increases in carbohydrates. Protein and fat proportions of treatment diets varied concordantly or were not reported. The control diets in the majority of trials in participants with T2DM were balanced for carbohydrates, fat and protein ($n = 13$) (Table 3).

As seen in the trials in participants without T2DM, the most common treatment diets compared across the trials in participants with T2DM were 'low'-carbohydrate, balanced-fat and high-protein treatment diets compared to control diets balanced for all three macronutrients ($n = 5$). This was followed by 'very low'-carbohydrate treatment diets with unspecified fat and protein contents compared to control diets with balanced-carbohydrates and unspecified fat and protein contents ($n = 2$) (Table 3).

Total energy prescription: In most of these trials, the total energy prescription was similar, or the approach used to restrict energy intake was similar in treatment and control groups ($n = 11$). In the remaining trials, the energy prescription was ad libitum in the treatment diets and restricted in the control diets (Samaha 2003; Saslow 2017a; Sato 2017; Westman 2008; Yamada 2014).

The Characteristics of included studies table contains key items from the template for intervention description and replication (TIDieR) checklist and guide (Hoffman 2014), including materials and procedures used to implement the diets; and who, how, where, and when the diets were implemented in each trial.

Funding of included trials

About 60% ($n = 28$) of the trials including participants without T2DM reported being funded only by non-commercial funders, including government and public research institutes, while 36% ($n = 17$) reported some or all funding by food/diet industry and related private companies, such as food and nutrition product manufacturers, organisations representing the interests of food producers (e.g. Pork Council, Dairy Farmers Association) and diet book and diet product organisations (Bales 2017; Benassi-Evans 2009; Dyson 2007; Farnsworth 2003; Frisch 2009; Griffin 2013; Josse 2011; Lasker 2008; Layman 2005; Layman 2009; Lean 1997; Liu 2013; Parr 2016; Racette 1995; Ruth 2013; Volek 2009; Wycherley 2012). Sources of funding were not reported by two trials in participants without T2DM (Aude 2004; Landers 2002).

About a third of trials including participants with T2DM (38%; $n = 6$) were funded solely by non-commercial funders, with seven trials (41%) reporting some or all funding by food/diet industry and related private companies (Dyson 2007; Hockaday 1978; Larsen 2011; Sato 2017; Watson 2016; Westman 2008; Wycherley 2010), and three trials not reporting funding source (Elhayany 2010; Pedersen 2014; Yamada 2014).

Excluded studies

We contacted 64 corresponding authors for further information to assist with study inclusion. We excluded 323 full-text articles with reasons, as follows.

- Linked to an included trial but no data used: 82
- No defined carbohydrate prescription used by study authors for the intervention and/or control diets: 28
- Duplicate: 27
- Ineligible study design: 26
- Not low-carbohydrate intervention diet: 27
- Carbohydrate contents of diets not adequately defined and could not be obtained from study authors: 22
- Focus of diets are on specific foods/replacements, food groups/components: 20
- Both diets are not low in carbohydrates: 18
- Ineligible duration: 17
- Ineligible participants: 16
- Diets not intended for weight loss: 9
- Both diets are low in carbohydrates: 7
- Diets differ by group in other ways that may influence outcomes: 7
- Control diet not balanced in carbohydrates: 4
- Co-interventions differ by group: 4
- Data from the weight-reducing phase of diets not available: 2
- Record of an additional study using participants from an included trial: 4
- Control diet not for weight loss: 1
- Other: 2

The Characteristics of excluded studies table contains the key studies excluded with reasons. The remaining references where we could not reach the authors or information provided was not sufficient to make a clear judgement ($n = 33$), were included as Studies awaiting classification. The nine ongoing studies are detailed in Characteristics of ongoing studies.

Risk of bias in included studies

Risk of bias assessments for each outcome included in the summary of findings tables, along with all domain judgements, are included in the forest plots. Figure 2 provides our judgements about each risk of bias item presented as percentages across all included trials for bias arising from the randomisation process, and across all outcomes in the summary of findings tables for all other items using RoB 2. Additional information, such as support for judgements, is located in the risk of bias section (located after the Characteristics of ongoing studies).

Figure 2. Risk of bias figure: systematic review authors' judgements about each risk of bias item presented as percentages across all included trials for bias arising from the randomisation process, and across all outcomes in the Summary of Findings tables for all other items using the Cochrane risk of bias 2 tool

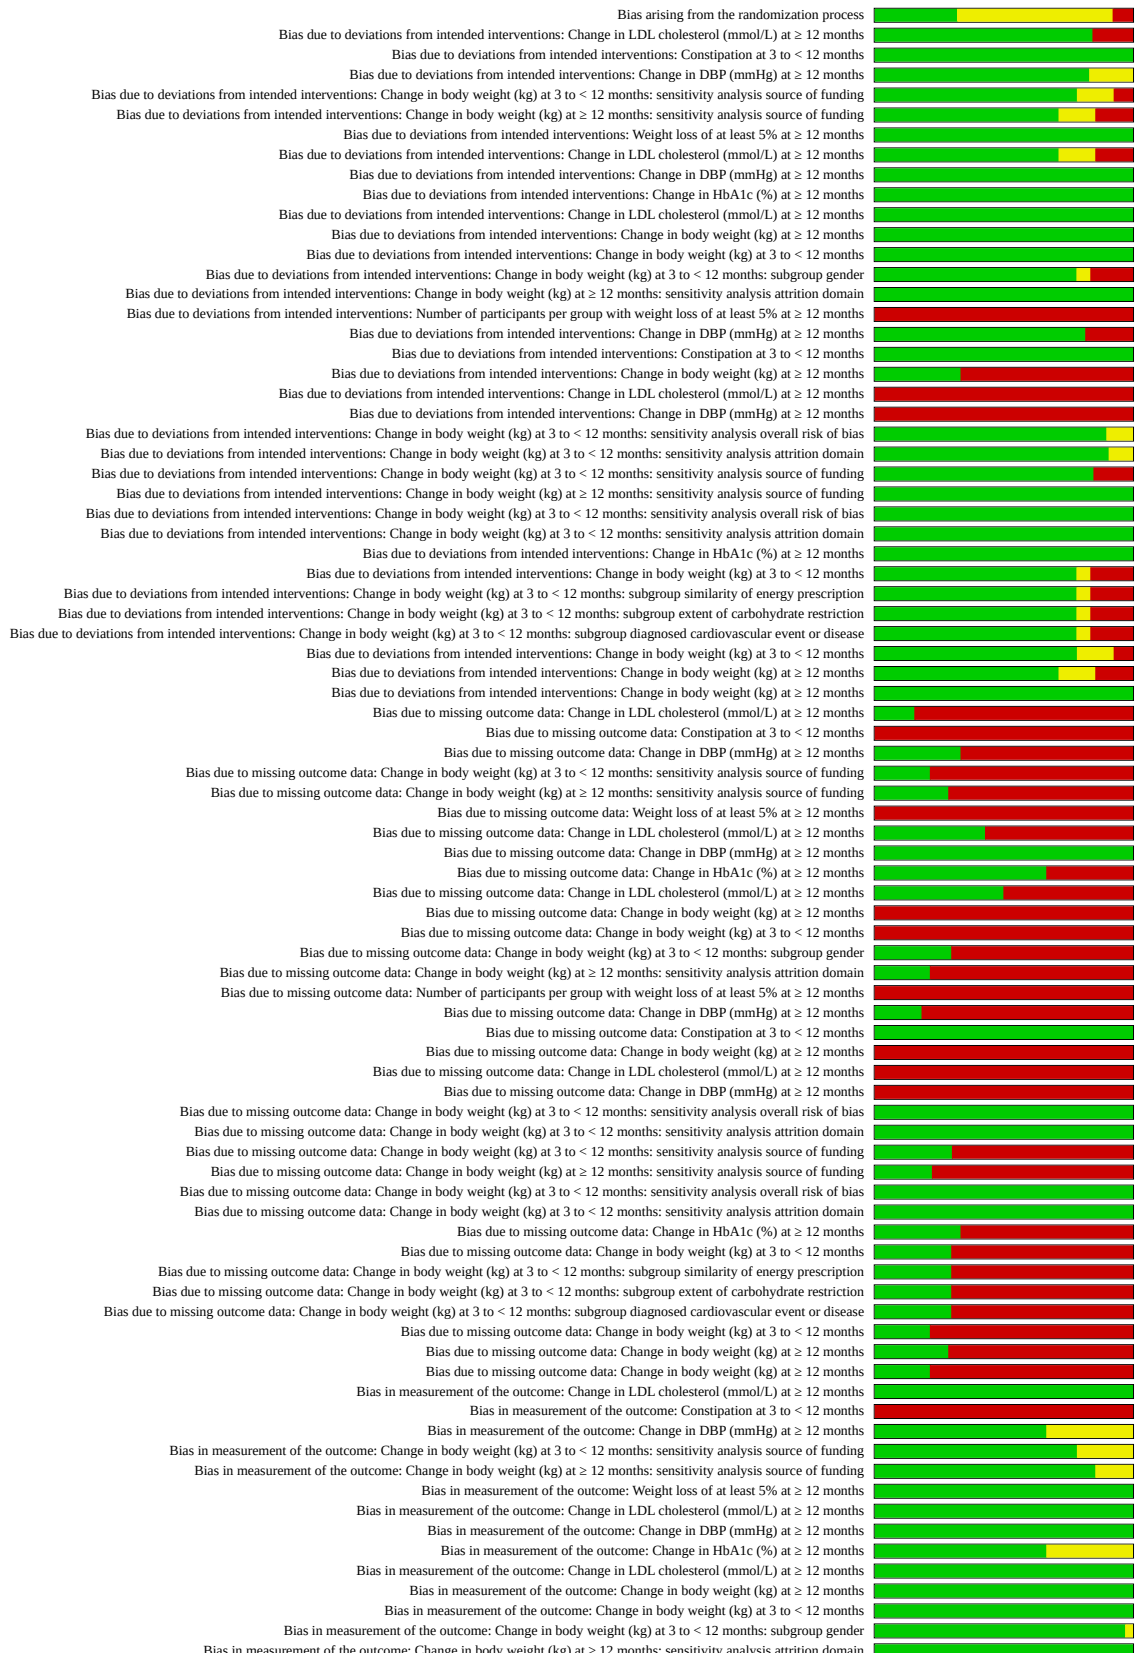

Figure 2. (Continued)

Figure 2. (Continued)

For most trials in participants without T2DM, the risk of bias arising from the randomisation process was judged as having 'some concerns' (n = 25), 10 trials were judged as low risk (Bales 2017; Dyson 2007; Ebbeling 2007; Gardner 2007; Griffin 2013; Haufe 2013; Jesudason 2013; Liu 2013; Marco-Benedi 2019; Sacks 2009), and four trials as high risk for this domain (Keogh 2007; Parr 2016; Tay 2008; Wycherley 2012). The overall risk of bias of outcomes across trials in participants without T2DM was similar and predominantly high. High overall risk of bias judgements were mostly as a result of bias due to missing outcome data, with high proportions of missing outcome data in many trials and this not being adequately handled by recommended statistical approaches. Bias due to deviations from intended interventions also contributed to high overall risk of bias. Problems with the measurement of outcomes did not contribute to high overall risk as most outcomes were not subjective or observer-reported; the exception was constipation, which was participant-reported and judged as high risk for most of the trials. None of the trials for any outcome in participants without T2DM reported prespecified analysis intentions in sufficient detail to enable assessment of selection of the reported result. Three trials did not contribute any numeric data to meta-analyses and risk of bias for these trials was not assessed, in line with guidance on implementing RoB 2 (Foster 2003; Pittas 2005; Racette 1995). Five trials did not report any outcomes included in the summary of findings tables, and we did not assess risk of bias of these (Juanola-Falgarona 2014; Kitabchi 2013; Ruth 2013; Samaha 2003; Stentz 2016).

Bias arising from the randomisation process was judged as low risk for approximately half of the trials in participants with T2DM (n = 8) (Dyson 2007; Evangelista 2021; Krebs 2012; Larsen 2011; Pedersen 2014; Saslow 2017a; Sato 2017; Watson 2016), with the remaining trials judged as having 'some concerns' (Elhayany 2010; Guldbrand 2012; Samaha 2003; Tay 2014; Westman 2008; Wycherley 2010; Yamada 2014). Across trials in participants with T2DM, the overall risk of bias of outcomes was similar and mostly high. As in the trials in participants without T2DM, the high overall risk of bias judgements were largely driven by bias due to missing outcome data, with high proportions of missing data not being adequately handled, and to a lesser extent by bias due to deviations from intended interventions. None of the trials in participants with T2DM reported prespecified analysis intentions in sufficient detail to enable us to assess the selection of the reported result. We did not assess risk of bias for one older study as it did not contribute usable data for an outcome included in the summary of findings tables (Hockaday 1978).

Effects of interventions

See: [Summary of findings 1](#) Summary of findings table - Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (weight-reducing phase only); [Summary of findings 2](#) Summary of findings table - Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (weight-reducing phase followed by weight-maintenance phase); [Summary of findings 3](#) Summary of findings table - Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (weight-reducing phase only); [Summary of findings 4](#) Summary of findings table - Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (weight-reducing phase followed by weight-maintenance phase)

See: [Summary of findings 1](#); [Summary of findings 2](#); [Summary of findings 3](#); [Summary of findings 4](#).

We analysed results from trials in overweight and obese participants without T2DM separately from those in participants with T2DM. We also separated analyses for weight-reducing phases of diets, and for weight-reducing phases followed by weight-maintenance phases. We report here the effects on the prespecified outcomes according to the four comparisons resulting from these stratifications.

We assessed the follow-up periods for the various outcomes as short term (three to < 12 months) or long term (≥ 12 months). The exact author-reported follow-up periods per outcome per trial appear as footnotes in each forest plot (i.e. using weeks, months or years). To summarise the follow-up period applicable per outcome, we also reported the specific follow-up range across all the trials that reported on that outcome.

None of the included trials reported on the following outcomes for any of the four comparisons: all-cause mortality, cardiovascular mortality, non-fatal myocardial infarction, non-fatal stroke and diagnosis of T2DM. Trials without usable data for outcomes in the summary of findings tables are summarised in [Table 4](#) for comparisons 1 and 2 and in [Table 5](#) for comparisons 3 and 4.

The assumed risk in comparison groups was expressed as the range of change values reported in the balanced-carbohydrate weight-

reducing diet groups across the studies that reported results for a given outcome. If only end values were reported for a given outcome, a mean change value was calculated by using the mean baseline value and subtracting it from the reported mean end value.

Comparison 1. Low-carbohydrate weight-reducing diets versus balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (weight-reducing phase only)

Summary of findings 1 presents the effects of low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets (weight-reducing phase only) in overweight and obese participants without T2DM on short-term (three to <12 months) and long-term (≥ 12 months) changes in body weight, as well as on the number of participants per group with weight loss of at least 5% over the long term, long-term change in DBP and LDL cholesterol, and short-term constipation.

Key details about studies in this comparison, including characteristics of the intervention, population, outcomes and method of synthesis, are included in the Overview of Synthesis and Included Studies (OSIS) table ([Table 6](#)).

Primary outcomes

Change in body weight (kg) at three to <12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference in change in body weight over three to 8.5 months compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Average weight reductions from baseline over the short term ranged from 12.18 kg to 4.45 kg with low-carbohydrate weight-reducing diets and from 11.34 kg to 2.3 kg with balanced-carbohydrate weight-reducing diets in the 37 trials that reported this outcome. The meta-analysis showed little to no difference in weight reduction on average between low-carbohydrate and

balanced-carbohydrate diet groups (MD -1.07 kg, (95% confidence interval (CI) -1.55 to -0.59, $I^2 = 51%$, 3286 participants, 37 RCTs, moderate-certainty evidence, Analysis 1.1) over three to 8.5 months. This lack of a difference in effect was confirmed by sensitivity analyses, including only trials with 'some concerns' of bias overall (Analysis 1.6; no trials at overall low risk of bias), those at low risk of attrition bias (Analysis 1.7) and those without reported diet/food industry funding (Analysis 1.8).

Subgrouping by similarity of energy prescription (Analysis 1.2), extent of carbohydrate restriction (Analysis 1.3), diagnosed cardiovascular event or disease at baseline (Analysis 1.4) or gender (Analysis 1.5) did not suggest important clinical differences in average effects between subgroups, with mean differences in weight reduction in overweight and obese participants at three to <12 months ranging between 0.25 kg and 2.71 kg across the various subgroups. Subgrouping by similarity of energy prescription and extent of carbohydrate restriction explained some heterogeneity. Heterogeneity was reduced ($I^2 = 0%$) in the subgroup including only trials with similar energy prescriptions/approaches to energy restriction in both diets, and in the subgroup including only trials investigating low-carbohydrate diets (> 50 g to 150 g per day or < 45% of total energy intake). We did not downgrade for inconsistency. The subgroup including only trials with no energy prescriptions or unrestricted energy prescriptions in both diets had small total numbers of participants ($n < 400$). This was also the case for the subgroup of trials only including men.

Nine trials reported this outcome in an unusable format (e.g. in figures or as percentage change in weight from baseline) and usable data were not provided when authors were contacted ([Table 4](#)). The funnel plot ([Figure 3](#)) shows most trials had similar standard errors of intervention effect estimates limiting the ability to assess asymmetry. The mean difference in fixed-effect analysis, which gives less weight to small studies (-0.91 kg, 95% CI -1.21 to -0.62), is similar to the mean difference in random-effects meta-analysis (-1.07 kg, 95% CI -1.55 to -0.59, Analysis 1.1), which gives more weight to smaller studies, suggesting that any small-study effects have little effect on the intervention effect estimate.

Figure 3. Funnel plot for change in weight at 3 to < 12 months (Analysis 1.1) in comparison 1

Thirteen of the 37 trials had follow-up at three months from baseline, nine at four months, 13 at six months, one at 26 weeks (about 6.5 months), and one trial at 34 weeks (about 8.5 months)

Change in body weight (kg) at ≥ 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference to change in body weight over one to two years compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Long-term average weight reductions in the 14 trials that reported this outcome ranged from 13.1 kg to 2.46 kg in low-carbohydrate diet groups and from 11.6 kg to 1.7 kg in balanced-carbohydrate diet groups. The meta-analysis of the mean difference in weight reduction between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference

at one to two years (MD -0.93 kg, 95% CI -1.81 to -0.04, $I^2 = 40%$, 1805 participants, 14 RCTs, moderate-certainty evidence, Analysis 1.9). Sensitivity analyses including only trials at low risk of attrition bias (Analysis 1.10) and trials without diet/food industry funding confirmed this lack of a difference in effect (Analysis 1.11). Other planned sensitivity analyses included fewer than two studies and thus were not performed.

Two trials reported this outcome in an unusable format (e.g. in figures or as percentage change in weight from baseline) and usable data were not provided when authors were contacted (Table 4). The funnel plot (Figure 4) suggests that smaller studies may be missing. The mean difference in fixed-effect analysis, which gave less weight to small studies (-0.81 kg, 95% CI -1.43 to -0.19), was similar to the mean difference in the random-effects meta-analysis (-0.93 kg, 95% CI -1.81 to -0.04, Analysis 1.9), which gave more weight to smaller studies, suggesting that any small-study effects had little effect on the intervention effect estimate.

Figure 4. Funnel plot for change in weight at ≥ 12 months (Analysis 1.9) in comparison 1

Ten of the 14 trials had follow-up at one year, one at 15 months, one at 74 weeks (about 18.5 months), with the two longest trials having follow-up at two years.

Number of participants per group with weight loss of at least 5% at three to < 12 months

The number of participants achieving at least 5% weight loss over the short term in the three trials reporting this outcome ranged from 14 to 41 with low-carbohydrate weight-reducing diets and from eight to 35 with balanced-carbohydrate weight-reducing diets. The meta-analysis of the risk ratio (RR) of the number of participants per group with weight loss of at least 5% at three to six months was 1.30 (95% CI 1.00 to 1.68, $I^2 = 47%$, 161 participants, 3 RCTs, Analysis 1.12) when comparing low-carbohydrate and balanced-carbohydrate diet groups. Two of the three trials that reported this outcome had follow-up at three months and the other at six months.

Number of participants per group with weight loss of at least 5% at ≥ 12 months

GRADE assessment suggests that the evidence is very uncertain about whether there is a difference in the number of participants per group with weight loss of at least 5% at one year, when comparing low-carbohydrate weight-reducing diets with balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (very low-certainty evidence; downgraded once for risk of bias and twice for imprecision).

Two studies reported on this outcome at one year (RR 1.11, 95% CI 0.94 to 1.31; $I^2 = 17%$; 137 participants, 2 RCTs, very low-certainty evidence, Analysis 1.13), with the number of participants achieving at least 5% weight loss ranging from 28 to 30 in the low-carbohydrate weight-reducing group and from 27 to 29 in the balanced-carbohydrate weight-reducing group. Another included trial also measured this outcome at two years but it was not reported in a usable format (Table 4).

Secondary outcomes

For comparison 1, no trials reported on the number of participants per group with reduction in BMI (kg/m^2) of at least 5% at ≥ 12 months.

Change in BMI (kg/m^2) at three to < 12 months

Twenty-one trials ($n = 1517$ participants) reported on short-term BMI change for comparison 1, with five of the 20 trials having follow-up at three months, five at four months and 11 trials at six months. Across the trials, average reduction in BMI from baseline ranged from 4.7 kg/m^2 to 1.8 kg/m^2 with low-carbohydrate diets and from 3.7 kg/m^2 to 0.98 kg/m^2 with balanced-carbohydrate diet groups. We did not pool these results into an overall effect estimate due to substantial heterogeneity ($I^2 = 53%$, $\text{Tau}^2 = 0.18$; $\text{Chi}^2 = 42.52$, $\text{df} = 20$ ($P = 0.002$)) but rather presented the individual effect sizes between the low-carbohydrate and balanced-carbohydrate diets per study (Analysis 1.14).

Change in BMI (kg/m²) at ≥ 12 months

Average reduction in BMI from baseline over the long term in the five trials reporting this outcome ranged from 5.2 kg/m² to 1.65 kg/m² in low-carbohydrate diet groups and from 4.1 kg/m² to 0.92 kg/m² in balanced-carbohydrate diet groups. When low-carbohydrate weight-reducing diets were compared to balanced-carbohydrate weight-reducing diets, the difference in BMI change on average at one to two years was -0.61 kg/m² (95% CI -0.99 to -0.23, *I*² = 0%, 490 participants, 5 RCTs, Analysis 1.15). Four trials had follow-up at one year and the remaining trial at two years.

Number of participants per group with reduction in BMI (kg/m²) of at least 5% at three to < 12 months

A single small study reported on this outcome at three months and the risk ratio was 1.57 (95% CI 0.79 to 3.12, 55 participants, 1 RCT, Analysis 1.16) with 14 participants in the low-carbohydrate weight-reducing group and eight participants in the balanced-carbohydrate weight-reducing group achieving at least 5% reduction in BMI.

Change in DBP (mmHg) at ≥ 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference to change in DBP compared to balanced-carbohydrate weight-reducing diets over one to two years in overweight and obese participants without T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Over one to two years, average change in DBP from baseline ranged from a 9 mmHg reduction to a 4 mmHg increase with low-carbohydrate diets and from an 11 mmHg reduction to 2.9 mmHg increase with balanced-carbohydrate diets across the 11 trials that reported this. The meta-analysis of the mean difference in change in DBP between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one to two years (MD -0.09 mmHg, 95% CI -1.29 to 1.12, *I*² = 44%, 1419 participants, 11 RCTs, moderate-certainty evidence, Analysis 1.17). Seven of the 11 trials had follow-up at one year, one at 15 months, one at 18 months and the other two trials at two years.

Change in SBP (mmHg) at ≥ 12 months

Average change in SBP from baseline in the 11 trials reporting this outcome ranged from reductions of 13.8 mmHg to 0.2 mmHg in low-carbohydrate diet groups and from a reduction of 14.6 mmHg to an increase of 1.7 mmHg in balanced-carbohydrate diet groups over one to two years of follow-up. For this comparison, the mean difference in change in SBP at one to two years was -1.37 mmHg (95% CI -2.99 to 0.24, *I*² = 34%, 1397 participants, 11 RCTs, Analysis 1.18). Seven of the 11 trials had follow-up at one year, one at 15 months, one at 18 months and the other two trials at two years.

Change in LDL cholesterol (mmol/L) at ≥ 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference in change in LDL cholesterol over one to two years compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Over one to two years, average change in LDL cholesterol from baseline across the 13 trials that reported this outcome ranged from reduction of 0.3 mmol/L to an increase of 0.6 mmol/L with low-carbohydrate diets and from a reduction of 0.31 mmol/L to an increase of 0.1 mmol/L with balanced-carbohydrate diets. The meta-analysis of the mean difference in change in LDL cholesterol between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one to two years (MD 0.04 mmol/L 95% CI -0.05 to 0.12, *I*² = 33%, 1494 participants, 13 RCTs, moderate-certainty evidence, Analysis 1.19). Nine of the 13 trials had follow-up at one year, one at 15 months, one at 18 months and the other two trials at two years. One of the included trials measured this outcome but it was not reported in a usable format (Table 4).

Change in HDL cholesterol (mmol/L) at ≥ 12 months

Average change in HDL cholesterol from baseline over one to two years ranged from a reduction of 0.1 mmol/L to an increase of 0.3 mmol/L in low-carbohydrate diet groups and from a reduction of 0.21 mmol/L to an increase of 0.18 mmol/L in balanced-carbohydrate diet groups in the 13 trials that reported this outcome. When low-carbohydrate weight-reducing diets were compared to balanced-carbohydrate weight-reducing diets, the mean difference in change in HDL cholesterol at one to two years was 0.06 mmol/L (95% CI 0.02 to 0.10, *I*² = 48%, 1519 participants, 13 RCTs, Analysis 1.20). Nine of the 13 trials had follow-up at one year, one at 15 months, one at 18 months and the other two trials at two years.

Change in non-HDL cholesterol (mmol/L) at ≥ 12 months

Two small studies reported on this outcome at one year and the mean difference in non-HDL cholesterol was 0.06 mmol/L (95% CI -0.2 to 0.33, *I*² = 47%, 225 participants, 2 RCTs, Analysis 1.21) with average change in non-HDL ranging from a reduction of 0.13 mmol/L to an increase of 0.24 mmol/L in low-carbohydrate weight-reducing groups and average reductions ranging from 0.1 mmol/L to 0.02 mmol/L in balanced-carbohydrate weight-reducing groups.

Change in total cholesterol (mmol/L) at ≥ 12 months

Over one to two years, average change in total cholesterol from baseline ranged from a reduction of 0.4 mmol/L to an increase of 0.7 mmol/L with low-carbohydrate diets and from a reduction of 0.42 mmol/L to an increase of 0.13 mmol/L with balanced-carbohydrate diets across the 11 trials that reported this. On average, there was no difference in change in total cholesterol at one to two years between the two types of diet (MD 0.01 mmol/L, 95% CI -0.1 to 0.12, *I*² = 41%, 1291 participants, 11 RCTs, Analysis 1.22). Eight of the 11 trials had follow-up at one year, one at 15 months and the other two trials at two years.

Change in triglycerides (mmol/L) at ≥ 12 months

Across the 13 trials that reported on triglycerides over one to two years, average change from baseline ranged from reductions of 0.58 mmol/L to 0.1 mmol/L with low-carbohydrate diets and from a reduction of 0.44 mmol/L to an increase of 0.02 mmol/L with balanced-carbohydrate diets. For this comparison, the mean difference in change in triglycerides at one to two years was -0.11 mmol/L (95% CI -0.16 to -0.06, *I*² = 0%, 1559 participants, 13 RCTs, Analysis 1.23). Nine of the 13 trials had follow-up at one year,

one at 15 months, one at 18 months and the other two trials at two years.

Participant-reported adverse effects

Participant-reported adverse effects were scantily reported by six included trials for comparison 1, with all outcomes except short-term constipation being reported only by single trials, and one of the trials reporting on most of these outcomes (Bazzano 2014). All 19 dichotomous outcomes reported very few events, had small total sample sizes and had wide 95% CIs. The four continuous outcomes all had small total samples sizes, mean differences close to 0 and wide 95% CIs.

Gastrointestinal

GRADE assessment suggests that the evidence is very uncertain about whether there is a difference in the number of participants per group with **constipation** at three to six months when comparing low-carbohydrate weight-reducing diets with balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (very low-certainty evidence, downgraded once for risk of bias and twice for imprecision).

The meta-analysis of the risk ratio of the number of participants per group reporting constipation at three to six months was 1.06 (95% CI 0.81 to 1.38, $I^2 = 0%$, 564 participants, 4 RCTs, very low-certainty evidence, Analysis 1.24) when comparing the two diet groups.

One trial reported constipation at one year (RR 0.63, 95% CI 0.32 to 1.25, 148 participants, 1 RCT, Analysis 1.25).

Two trials reported on events of **diarrhoea** finding no difference over the shorter term (at three months and at six months) (RR 0.98, 95% CI 0.33 to 2.93, 244 participants, 2 RCTs, Analysis 1.26) or at one year (RR 0.32, 95% CI 0.03 to 3.05, 148 participants, 1 RCT, Analysis 1.27). This was also the case for **nausea** over the shorter term (RR 0.73, 95% CI 0.05 to 10.68, 244 participants, 2 RCTs, Analysis 1.28) and at one year (RR 0.14, 95% CI 0.01 to 2.65, 148 participants, 1 RCT, Analysis 1.29).

One trial reported on events of **flatulence** at six months (RR 0.75, 95% CI 0.44 to 1.30, 148 participants, 1 RCT, Analysis 1.30) and again at one year (RR 0.68, 95% CI 0.39 to 1.17, 148 participants, 1 RCT, Analysis 1.31), as well on events of **heartburn** at six months (RR 0.53, 95% CI 0.21 to 1.36, 148 participants, 1 RCT, Analysis 1.32) and at one year (RR 0.49, 95% CI 0.23 to 1.01, 148 participants, 1 RCT, Analysis 1.33).

One trial reported on **halitosis** at six months (RR 1.99, 95% CI 1.32 to 2.99, 263 participants, 1 RCT, Analysis 1.34) and another trial reported **stomach upsets** at three months (RR 1.00, 95% CI 0.41 to 2.45, 96 participants, 1 RCT, Analysis 1.35).

Appetite and hunger

Appetite change was reported by one trial at six months follow-up (RR 0.19, 95% CI 0.01 to 3.99, 148 participants, 1 RCT, Analysis 1.36) and at one year (RR 0.49, 95% CI 0.05 to 5.25, 148 participants, 1 RCT, Analysis 1.37).

In another trial, **hunger** and **desire to eat** were gauged using a visual analog score as change from baseline at one year for this comparison. The mean score for hunger was -1.05 (SEM 0.56; $n = 21$) in the low-carbohydrate diet group and -0.18 (SEM 0.66; $n = 15$) in

the balanced-carbohydrate diet group. Mean scores for desire to eat were -1.02 (SEM 0.59; $n = 21$) in the low-carbohydrate diet group and -0.16 (SEM 0.76; $n = 15$) in the balanced-carbohydrate diet group (Griffin 2013).

Fatigue

One trial reported on events of **fatigue** at six months (RR 0.80, 95% CI 0.47 to 1.36, 148 participants, 1 RCT, Analysis 1.38) and at one year (RR 0.91, 95% CI 0.49 to 1.71, 148 participants, 1 RCT, Analysis 1.39).

Headaches

Two trials reported on **headaches** with no difference over the shorter term (at three months and at six months) (RR 1.25, 95% CI 0.26 to 6.02, $I^2 = 55%$, 244 participants, 2 RCTs, Analysis 1.40) or at one year (RR 0.49, 95% CI 0.25 to 0.93, 148 participants, 1 RCT, Analysis 1.41).

Psychosocial problems (mood disturbances)

A single trial measured events of **reported anxiety** at three months follow-up for comparison 1 (RR 1.0, 95% CI 0.07 to 15.26, 60 participants, 1 RCT, Analysis 1.42).

One trial reported **total mood disturbance scores** according to the Profile of Mood States (POMS) at three months (MD 1.91, 95% CI -8.06 to 11.88, 118 participants, 1 RCT, Analysis 1.43) and one year (MD 2.87, 95% CI -8.48 to 14.22, 118 participants, 1 RCT, Analysis 1.44).

At four months follow-up, one trial reported **depressive symptoms** according to the Beck Depression Inventory (MD -0.30, 95% CI -1.36 to 0.76, 217 participants, 1 RCT, Analysis 1.45) and **anxiety symptoms** according to the State-Trait Anxiety Inventory (MD -0.20, 95% CI -1.44 to 1.04, 217 participants, 1 RCT, Analysis 1.46).

Comparison 2. Low-carbohydrate weight-reducing diets versus balanced-carbohydrate weight-reducing diets in overweight and obese participants without T2DM (weight-reducing phase followed by weight-maintenance phase)

Summary of findings 2 presents the effects of low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets (weight-reducing phase followed by weight-maintenance phase) in overweight and obese participants without T2DM on long-term (≥ 12 months) changes in body weight, DBP and LDL cholesterol.

Key details about studies in this comparison, including characteristics of the intervention, population, outcomes and method of synthesis are detailed in the OSIS table (Table 6).

Primary outcomes

The only primary outcome reported by the included trials for comparison 2 was change in body weight at ≥ 12 months.

Change in body weight (kg) at ≥ 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets that include a weight-maintenance phase may result in little to no difference in change in body weight over one to two years compared to balanced-carbohydrate weight-reducing diets that include a weight-maintenance phase in overweight and obese

participants without T2DM (low-certainty evidence, downgraded once for risk of bias and once for imprecision).

Over the long term, average weight change from baseline ranged from a reduction of 5.4 kg to an increase of 0.86 kg with low-carbohydrate diets and from reductions of 5.5 kg to 1.5 kg with balanced-carbohydrate diets across the three trials that reported this outcome. The meta-analysis of the mean difference in weight reduction between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one to two years (MD -0.30 kg, 95% CI -2.77 to 2.16, $I^2 = 0\%$, 73 participants, 3 RCTs, low-certainty evidence, Analysis 2.1). One of the trials had a weight-reducing phase of 12 weeks followed by a weight-maintenance phase of 40 weeks, measuring change in weight at one year. The other two trials measured change in weight at two years, with one trial testing a three-month weight-reducing phase followed by a 21-month maintenance phase, and the other trial testing a 6-month weight-reducing phase followed by a maintenance-phase that averaged 18 months in duration. This lack of a difference in effect was confirmed by a sensitivity analysis including only the two trials without reported diet/food industry funding (MD -0.80 kg, 95% CI -3.48 to 1.88, $I^2 = 0\%$, 63 participants, 2 RCTs, analysis not shown).

Secondary outcomes

The only secondary outcomes reported by the included trials for comparison 2 were changes in DBP, SBP, LDL and HDL cholesterol, total cholesterol and triglycerides.

Changes in DBP and SBP (mmHg) at ≥ 12 months

GRADE assessment suggests that the evidence is very uncertain about the effect of low-carbohydrate weight-reducing diets that include a weight-maintenance phase compared to balanced-carbohydrate weight-reducing diets that include a weight-maintenance phase on change in DBP at one year in overweight and obese participants without T2DM (very low-certainty evidence, downgraded once for risk of bias and twice for imprecision).

One very small trial compared these diets using a weight-reducing phase of 12 weeks followed by a maintenance phase of 40 weeks, and reported on changes in DBP (MD -6.0 mmHg, 95% CI -17.55 to 5.55, 13 participants, 1 RCT, very low-certainty evidence, Analysis 2.2) and SBP (MD -15.0 mmHg, 95% CI -32.36 to 2.36, 13 participants, 1 RCT, Analysis 2.3) at one year. The study reported average DBP reductions from baseline of 4 mmHg in the low-carbohydrate diet group and of 6 mmHg in the balanced-carbohydrate diet group. For SBP, the study reported an average decrease from baseline of 2 mmHg in the low-carbohydrate group and an increase of 2 mmHg in the balanced-carbohydrate group.

Changes in LDL, HDL and total cholesterol and triglycerides (mmol/L) at ≥ 12 months

Two small trials reported changes in these blood lipids at one to two years. GRADE assessment suggests that the evidence is very uncertain about the effect of low-carbohydrate weight-reducing diets that include a weight-maintenance phase compared to balanced-carbohydrate weight-reducing diets that include a weight-maintenance phase on change in LDL at one to two years in overweight and obese participants without T2DM (very low-certainty evidence, downgraded once for risk of bias and twice for imprecision).

One trial used a weight-reducing phase of 12 weeks followed by a maintenance phase of 40 weeks, and the other trial used a weight-reducing phase of six months followed by a maintenance phase of 18 months with changes reported at one and two years, respectively for LDL cholesterol (MD -0.08 mmol/L, 95% CI -0.44 to 0.28, $I^2 = 0\%$, 56 participants, 2 RCTs, very low-certainty evidence, Analysis 2.4), HDL cholesterol (MD -0.05 mmol/L, 95% CI -0.37 to 0.28, $I^2 = 5\%$, 56 participants, 2 RCTs, Analysis 2.5), total cholesterol (MD -0.08 mmol/L, 95% CI -0.43 to 0.27, $I^2 = 0\%$, 56 participants, 2 RCTs, Analysis 2.6) and triglycerides (MD -0.08 mmol/L, 95% CI -0.34 to 0.17, $I^2 = 0\%$, 56 participants, 2 RCTs, Analysis 2.7).

Average LDL cholesterol reductions from baseline ranged from 0.79 mmol/L to 0.2 mmol/L with low-carbohydrate diets and from 1.15 mmol/L to 0.14 mmol/L with balanced-carbohydrate diets. For HDL-cholesterol, average changes ranged from a decrease of 0.2 mmol/L to an increase of 0.11 mmol/L with low-carbohydrate diets and from increases of 0.03 mmol/L to 0.04 mmol/L with balanced-carbohydrate diets. Average reductions in total cholesterol ranged from 0.24 mmol/L to 0.79 mmol/L with low-carbohydrate diets and from 0.17 mmol/L to 1.14 mmol/L with balanced-carbohydrate diets. For triglycerides, average reductions ranged from 0.19 mmol/L to 0.28 mmol/L with low-carbohydrate diets and from 0.04 mmol/L to 0.13 mmol/L with balanced-carbohydrate diets.

Comparison 3. Low-carbohydrate weight-reducing diets versus balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (weight-loss phase only)

Summary of findings 3 presents the effects of low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets (weight-reducing phase only) in overweight and obese participants with T2DM on short-term (three to < 12 months) and long-term (≥ 12 months) changes in body weight, as well as on the number of participants per group with weight loss of at least 5% over the long term, long-term change in DBP, HbA1c and LDL cholesterol, and short-term constipation.

Key details about studies in this comparison, including characteristics of the intervention, population, outcomes and method of synthesis can be found in the OSIS table (Table 6).

Primary outcomes

Change in body weight (kg) at three to < 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference in change in body weight over three to six months compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Average weight reductions from baseline over three to six months ranged from 12 kg to 2.41 kg with low-carbohydrate weight-reducing diets and from 11.5 kg to 0.33 kg with balanced-carbohydrate weight-reducing diets in the 14 trials reporting this outcome. The meta-analysis showed little to no difference in weight reduction on average between low-carbohydrate and balanced-carbohydrate diet groups over three to six months (MD -1.26 kg, 95% CI -2.44 to -0.09, $I^2 = 47\%$, 1114 participants, 14 RCTs, moderate-certainty evidence, Analysis 3.1). This lack of a difference in effect was also seen with sensitivity analyses including only trials with 'some concerns' of bias overall (Analysis 3.2, no trials

at overall low risk of bias), at low risk of attrition bias (Analysis 3.3) and without reported diet/food industry funding (Analysis 3.4).

One included trial also measured change in body weight at three to < 12 months but reported it in an unusable format (Table 5). The funnel plot (Figure 5) suggests that smaller studies may be missing.

The mean difference in fixed-effect analysis, which gives less weight to small studies (-0.92 kg, 95% CI -1.65 to -0.19), is similar to the mean difference in random-effects meta-analysis (-1.26 kg, 95% CI -2.44 to -0.09, Analysis 3.1), which gives more weight to smaller studies, suggesting that any small-study effects have little effect on the intervention effect estimate.

Figure 5. Funnel plot for change in weight at 3 to < 12 months (Analysis 3.1) in comparison 3

Four of the 14 trials had follow-up at three months from baseline, one trial at four months and nine at six months.

Change in body weight (kg) at ≥ 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference in change in body weight over one to two years compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Average weight reductions from baseline over one to two years in the seven trials reporting this outcome ranged from 8.9 kg to 2 kg with low-carbohydrate weight-reducing diets and from 7.4 kg to 1.7 kg with balanced-carbohydrate weight-reducing diets. The meta-analysis showed little to no difference in weight reduction on average between low-carbohydrate and balanced-carbohydrate diet groups over one to two years (MD -0.33 kg, 95% CI -2.13 to 1.46, $I^2 = 10%$, 813 participants, 7 RCTs, moderate-certainty evidence, Analysis 3.5). This lack of a difference in effect was also seen with the sensitivity analysis including only trials without diet/food industry funding (Analysis 3.6). Other planned sensitivity

analyses included only one or two studies and thus were not performed.

Of the seven trials, four had follow-up at one year and three had follow-up at two years. The oldest included trial also measured change in body weight at ≥ 12 months but reported it in an unusable format (Table 5).

Number of participants per group with weight loss of at least 5% at three to < 12 months

A single small study reported on this outcome at three months and the risk ratio was 1.01 (95% CI 0.77 to 1.33, 45 participants, 1 RCT, Analysis 3.7) with 19 participants in the low-carbohydrate group and 18 participants in the balanced-carbohydrate group achieving at least 5% weight loss from baseline.

Number of participants per group with weight loss of at least 5% at ≥ 12 months

GRADE assessment suggests that the evidence is very uncertain about whether there is a difference in the number of participants per group with weight loss of at least 5% at one to two years, when comparing low-carbohydrate weight-reducing diets

with balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (very low-certainty evidence, downgraded once for risk of bias, once for indirectness and twice for imprecision).

Two studies reported on this outcome at one and two years (RR 0.90, 95% CI 0.68 to 1.20; $I^2 = 0$; 106 participants, 2 RCTs, very low-certainty evidence,) with the number of participants achieving at least 5% weight loss from baseline ranging from 10 to 22 in the low-carbohydrate weight-reducing group and 14 to 20 in the balanced-carbohydrate weight-reducing group.

Secondary outcomes

For comparison 3, no studies reported on the number of participants per group with reduction in BMI (kg/m^2) of at least 5%.

Change in BMI (kg/m^2) at three to < 12 months

Eleven trials ($n = 515$ participants) reported on short-term BMI change. Across these trials, average reductions in BMI from baseline ranged from 4 kg/m^2 to 0.87 kg/m^2 with low-carbohydrate diets and from 4 kg/m^2 to 0.1 kg/m^2 with balanced-carbohydrate diets. We did not pool these results into an overall effect estimate due to substantial heterogeneity ($I^2 = 57\%$, $\text{Tau}^2 = 0.56$; $\text{Chi}^2 = 23.11$, $\text{df} = 10$ ($P = 0.01$)) but rather presented the individual effect sizes between the two types of diet per study (Analysis 3.9). Three of the 10 trials had follow-up at three months, one at four months and seven at six months.

Change in BMI (kg/m^2) at ≥ 12 months

Average reductions in BMI from baseline over the long term in the four trials reporting this outcome ranged from 3.3 kg/m^2 to 0.8 kg/m^2 with low-carbohydrate diets and from 2.6 kg/m^2 to 0.9 kg/m^2 with balanced-carbohydrate diets. When low-carbohydrate weight-reducing diets were compared to balanced-carbohydrate weight-reducing diets, the difference in BMI change on average at one to two years was -0.29 kg/m^2 (95% CI -1.06 to 0.48, $I^2 = 13\%$, 329 participants, 4 RCTs, Analysis 3.10). Two trials had follow-up at one year and the remaining two at two years.

Change in DBP (mmHg) at ≥ 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference to change in DBP compared to balanced-carbohydrate weight-reducing diets over one to two years in overweight and obese participants with T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Over one to two years, average changes from baseline in DBP ranged from a reduction of 5 mmHg to an increase 3 mmHg in low-carbohydrate diet groups and from a reduction of 6 mmHg to an increase of 4.3 mmHg in balanced-carbohydrate diet groups across the six trials reporting on this outcome. The meta-analysis of the mean difference in change in DBP between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one to two years (MD -0.28 mmHg 95% CI -1.84 to 1.28, $I^2 = 0\%$, 631 participants, 6 RCTs, moderate-certainty evidence, Analysis 3.11). Three of the six trials had follow-up at one year and the other three at two years.

Change in SBP (mmHg) at ≥ 12 months

Average change in SBP from baseline in the six trials reporting this outcome ranged from a reduction of 9 mmHg to an increase of 3.2 mmHg with low-carbohydrate diets and from a reduction of 11 mmHg to an increase of 2.4 mmHg with balanced-carbohydrate diets over one to two years of follow-up. The mean difference in change in SBP at one to two years was 0.32 mmHg (95% CI -2.30 to 2.93, $I^2 = 0\%$, 629 participants, 6 RCTs, Analysis 3.12). Three of the six trials had follow-up at one year and the other three at two years.

Change in HbA1c (%) at 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference to change in HbA1c compared to balanced-carbohydrate weight-reducing diets over one to two years in overweight and obese participants with T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Average change in HbA1c from baseline over one to two years ranged from a reduction of 2% to an increase of 0.1% with low-carbohydrate diets and from a reduction of 1.8% to an increase of 0.2% with balanced-carbohydrate diets across the six trials that reported this outcome. The meta-analysis of the mean difference in change in HbA1c between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one to two years (MD -0.14% 95% CI -0.38 to 0.10, $I^2 = 31\%$, 668 participants, 6 RCTs, moderate-certainty evidence, Analysis 3.13). Four of the six trials had follow-up at one year and the other two had follow-up at two years. One included trial also measured change in HbA1c in diabetic participants only at one year but reported it in an unusable format (Table 5).

Change in LDL cholesterol (mmol/L) at ≥ 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets probably result in little to no difference in change in LDL-cholesterol over one to two years compared to balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (moderate-certainty evidence, downgraded once for risk of bias).

Average change from baseline over one to two years across the seven trials reporting on change in LDL cholesterol ranged from a reduction of 0.61 mmol/L to an increase of 0.2 mmol/L in low-carbohydrate diet groups and from a reduction of 0.55 mmol/L to an increase of 0.1 mmol/L in balanced-carbohydrate diet groups. The meta-analysis of the mean difference in change in LDL cholesterol between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one to two years (MD 0.12 mmol/L, 95% CI -0.03 to 0.26, $I^2 = 34\%$, 753 participants, 7 RCTs, moderate-certainty evidence, Analysis 3.14). Four of the seven trials had follow-up at one year; the other three had follow-up at two years.

Change in HDL cholesterol (mmol/L) at ≥ 12 months

Over one to two years, average change from baseline across the seven trials reporting on change in HDL cholesterol ranged from a reduction of 0.03 mmol/L to an increase of 0.23 mmol/L in low-carbohydrate diet groups and from a reduction of 0.13 mmol/L to an increase of 0.11 mmol/L in balanced-carbohydrate diet groups. We did not pool these results into an overall effect estimate due to

substantial heterogeneity ($I^2 = 67\%$, $\text{Tau}^2 = 0.01$; $\text{Chi}^2 = 18.34$, $\text{df} = 6$ ($P = 0.005$)) but rather presented the individual effect sizes between the low-carbohydrate and balanced-carbohydrate diets per study (Analysis 3.15). Four of the seven trials had follow-up at one year and the other three had follow-up at two years.

Change in non-HDL cholesterol (mmol/L) at ≥ 12 months

Two studies reported on this outcome at one and two years and the mean difference in non-HDL cholesterol was 0.09 mmol/L (95% CI -0.39 to 0.58, $I^2 = 0\%$, 159 participants, 2 RCTs, Analysis 3.16) with average increases in non-HDL ranging from 0.13 mmol/L to 0.2 mmol/L in the low-carbohydrate weight-reducing group and from 0.1 mmol/L to 0.17 mmol/L in the balanced-carbohydrate weight-reducing group.

Change in total cholesterol (mmol/L) at ≥ 12 months

Average change from baseline over one to two years across the seven trials reporting on change in total cholesterol ranged from a reduction of 0.88 mmol/L to an increase of 0.2 mmol/L with low-carbohydrate diets and from reductions of 0.96 mmol/L to 0.1 mmol/L with balanced-carbohydrate diets. The mean difference in change in total cholesterol at one to two years was 0.21 mmol/L (95% CI 0.06 to 0.37, $I^2 = 25\%$, 838 participants, 7 RCTs, Analysis 3.17). Four of the seven trials had follow-up at one year and the other three trials at two years.

Change in triglycerides (mmol/L) at ≥ 12 months

Over one to two years, average change in triglycerides from baseline triglycerides ranged from reductions of 1.52 mmol/L to 0.1 mmol/L in low-carbohydrate diet groups and from a reduction of 1.46 mmol/L to an increase of 0.16 mmol/L in balanced-carbohydrate diet groups across the seven trials reporting on this outcome. We did not pool these results into an overall effect estimate due to substantial heterogeneity ($I^2 = 75\%$, $\text{Tau}^2 = 0.07$; $\text{Chi}^2 = 23.97$, $\text{df} = 6$ ($P = 0.0005$)) but rather presented the individual effect sizes between the low-carbohydrate and balanced-carbohydrate diets per study (Analysis 3.18). Five of the seven trials had follow-up at one year and the remaining two trials at two years. Another trial reported change in triglycerides at two years as medians and interquartile ranges as the data were not normally distributed (Krebs 2012).

Participant-reported adverse effects

Participant-reported adverse effects were scantily reported by three included trials for comparison 3, with all outcomes except short-term constipation being reported only by single trials. All adverse effect outcomes reported in these trials had very few events or mean differences close to 0 and small total sample sizes.

Gastrointestinal

GRADE assessment suggests that the evidence is very uncertain about whether there is a difference in the number of participants per group with **constipation** at three to six months when comparing low-carbohydrate weight-reducing diets with balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (very low-certainty evidence, downgraded once for risk of bias and twice for imprecision).

The meta-analysis of the risk ratio of the number of participants per group reporting constipation at six months was 1.37 (95% CI

0.86 to 2.18, $I^2 = 0\%$, 177 participants, 2 RCTs, very low-certainty evidence, Analysis 3.19) when comparing low-carbohydrate and balanced-carbohydrate diet groups. One included trial also measured constipation at three months but reported data in an unusable format (Table 5).

One trial reported constipation at one year (RR 2.71, 95% CI 0.11 to 64.65, 78 participants, 1 RCT, Analysis 3.20).

One trial reported on events of **diarrhoea** at six months (RR 1.07, 95% CI 0.62 to 1.84, 84 participants, 1 RCT, Analysis 3.21). Another trial (using an adaptation of the Health Symptom Checklist) (Saslow 2017a) reported "no statistically significant changes" for diarrhoea at three months (data were not reported or provided when authors were contacted), and also reported heartburn symptoms at three months (MD -0.30, 95% CI -0.66 to 0.06, 33 participants, 1 RCT, Analysis 3.22).

Appetite

One trial reported on **appetite change** from baseline at three months using the three-factor eating questionnaire (MD -0.70, 95% CI -3.03 to 1.63, 33 participants, 1 RCT, Analysis 3.23).

Headaches

One trial reported on events of **headaches** at six months (RR 1.15, 95% CI 0.75 to 1.78, 84 participants, 1 RCT, Analysis 3.24). Another trial reported no statistical difference between participants in the low-carbohydrate diet group and the balanced-diet group for headaches at three months (used adaptation of the Health Symptom Checklist), but data were not reported or provided when authors were contacted (Saslow 2017a).

Psychosocial problems (mood disturbances)

At three months follow-up, one trial reported **depressive symptoms** according to the 20-item Center for Epidemiologic Studies Depression Scale (CES-D) (MD -0.20, 95% CI -9.20 to 8.80, 33 participants, 1 RCT, Analysis 3.25).

Comparison 4. Low-carbohydrate weight-reducing diets versus balanced-carbohydrate weight-reducing diets in overweight and obese participants with T2DM (weight-reducing phase followed by weight-maintenance phase)

Summary of findings 4 presents the effects of low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets (weight-reducing phase followed by weight-maintenance phase) in overweight and obese participants with T2DM on short-term (three to <12 months) and long-term (≥ 12 months) changes in body weight, DBP, HbA1c and LDL cholesterol, and short-term constipation.

Key details about studies in this comparison, including characteristics of the intervention, population, outcomes and method of synthesis are detailed in the OSIS table (Table 6).

Primary outcomes

The only primary outcomes reported by the included trials for comparison 4 were change in body weight at three to < 12 months and change in body weight at ≥ 12 months.

Change in body weight (kg) at three to < 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets that include a weight-maintenance phase may result in little to no difference in change in body weight at six months compared to balanced-carbohydrate weight-reducing diets that include a weight-maintenance phase in overweight and obese participants with T2DM (low-certainty evidence, downgraded once for risk of bias and once for imprecision).

The single study reporting change in weight at six months found average weight reductions of 1 kg with the low-carbohydrate diet and 0.2 kg with the balanced-carbohydrate diet. The mean difference in weight reduction between the two diets in this study demonstrated little to no difference at six months (MD -0.80 kg, 95% CI -2.46 to 0.86, 61 participants, 1 RCT, low-certainty evidence, Analysis 4.1). This trial tested diets with a three-month weight-reducing phase followed by a three-month weight-maintenance phase.

Change in body weight (kg) at ≥ 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets that include a weight-maintenance phase may result in little to no difference in change in body weight over one to two years compared to balanced-carbohydrate weight-reducing diets that include a weight-maintenance phase in overweight and obese participants with T2DM (low-certainty evidence, downgraded once for risk of bias and once for imprecision).

Average changes in weight from baseline over one to two years in the three trials reporting this outcome ranged from a reduction of 2.23 kg to an increase 1.3 kg with low-carbohydrate diets and from reductions of 2.17 kg to 1.5 kg with balanced-carbohydrate diets. The meta-analysis of the mean difference in weight reduction between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one to two years (MD -0.07 kg, 95% CI -1.31 to 1.17, $I^2 = 0\%$, 158 participants, 3 RCTs, low-certainty evidence, Analysis 4.2). The shortest of the trials measured change in weight at one year with the diets having a three-month weight-loss phase followed by a nine-month weight-reducing phase. The second trial had follow-up at 18 months and tested diets with a six-month weight-reducing phase followed by a 12-month maintenance phase. The third trial had follow-up at two years, and tested diets with a three-month weight-reducing followed by a 21-month weight-maintenance phase. All trials had high risk of attrition bias and overall bias, and had diet/food industry funding, precluding sensitivity analyses.

Secondary outcomes

The secondary outcomes reported by the included trials for comparison 4 were change in BMI at three to < 12 months, change in BMI at ≥ 12 months, change in HbA1c, DBP, SBP, LDL and HDL cholesterol, total cholesterol and triglycerides.

Change in BMI (kg/m²) at three to < 12 months

One trial compared these diets using a three-month weight-reducing phase followed by a three-month weight-maintenance phase and reported average BMI reductions from baseline of 0.3 kg/m² in the low-carbohydrate group and 0.01 kg/m² in the balanced-carbohydrate group after six months. The meta-analysis of the

mean difference in BMI change at six months was -0.29 kg/m² (95% CI -0.83 to 0.25, 61 participants, 1 RCT, Analysis 4.3).

Change in BMI (kg/m²) at ≥ 12 months

The single trial reporting on this outcome in comparison 4 found average BMI reductions from baseline of 0.75 kg/m² with the low-carbohydrate diet and 0.63 kg/m² with the balanced diet after 18 months (six-month weight-reducing phase followed by 12-month weight-maintenance phase). The mean difference in BMI change at 18 months in this trial was -0.12 kg/m² (95% CI -0.86 to 0.62, 47 participants, 1 RCT, Analysis 4.4).

Changes in DBP and SBP (mmHg) at ≥ 12 months

GRADE assessment suggests that the evidence is very uncertain about the effect of low-carbohydrate weight-reducing diets that include a weight-maintenance phase compared to balanced-carbohydrate weight-reducing diets that include a weight-maintenance phase on change in DBP at one year in overweight and obese participants with T2DM (very low-certainty evidence, downgraded once for risk of bias and twice for imprecision).

One trial compared these diets in comparison 4 using a three-month weight-reducing phase followed by a nine-month maintenance phase, and reported on changes in DBP (MD -0.44 mmHg, 95% CI -4.89 to 4.01, 99 participants, 1 RCT, very low-certainty evidence, Analysis 4.5) and SBP (MD -4.27 mmHg, 95% CI -8.74 to 0.20, 99 participants, 1 RCT, Analysis 4.6) at one year. The study reported average DBP increases from a baseline of 0.21 mmHg in the low-carbohydrate diet group and of 0.65 mmHg in the balanced-carbohydrate diet group at one year. For SBP, the study reported an average decrease from baseline of 5.03 mmHg in the low-carbohydrate group and 0.76 mmHg in the balanced-carbohydrate group.

Change in HbA1c (%) at 12 months

GRADE assessment suggests that low-carbohydrate weight-reducing diets that include a weight-maintenance phase may result in little to no difference in change in HbA1c over one to two years compared to balanced-carbohydrate weight-reducing diets that include a weight-maintenance phase in overweight and obese participants with T2DM (low-certainty evidence, downgraded once for risk of bias and once for imprecision).

Average changes in HbA1c from baseline over one to two years in the three trials reporting this outcome ranged from a reduction of 0.39% to an increase of 0.3% with low-carbohydrate diets and from a reduction of 0.37% to an increase of 0.4% with balanced-carbohydrate diets. The meta-analysis of the mean difference in change in HbA1c between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one to two years (MD 0.02%, 95% CI -0.30 to 0.33, $I^2 = 0\%$, 160 participants, 3 RCTs, low-certainty evidence, Analysis 4.7). The shortest of the trials measured change in HbA1c at one year with diets having a three-month weight-loss phase followed by a nine-month weight-reducing phase. The second trial had follow-up at 18 months and tested diets with a six-month weight-reducing phase followed by a 12-month maintenance phase. The third trial had follow-up at two years, and tested diets with a three-month weight-reducing followed by a 21-month weight-maintenance phase.

Change in LDL, HDL and total cholesterol and triglycerides (mmol/L) at ≥ 12 months

Two trials reported changes in these blood lipids at one to two years. GRADE assessment suggests that low-carbohydrate weight-reducing diets that include a weight-maintenance phase may result in little to no difference in change in LDL over one year to 18 months compared to balanced-carbohydrate weight-reducing diets that include a weight-maintenance phase in overweight and obese participants with T2DM (low-certainty evidence, downgraded once for risk of bias and once for imprecision).

One trial had follow-up at one year with diets having a three-month weight-loss phase followed by a nine-month weight-reducing phase. The other trial assessed follow-up at 18 months and tested diets with a six-month weight-reducing phase followed by a 12-month maintenance phase. The meta-analysis of the mean difference in change in LDL cholesterol between the low-carbohydrate and balanced-carbohydrate diets demonstrated little to no difference at one year to 18 months (MD -0.06 mmol/L, 95% CI -0.26 to 0.13, $I^2 = 0\%$, 145 participants, 2 RCTs, low-certainty evidence, Analysis 4.8). The two trials reported on HDL cholesterol (MD 0.0 mmol/L, 95% CI -0.07 to 0.08, $I^2 = 0\%$, 148 participants, 2 RCTs, Analysis 4.9) and triglycerides (MD -0.06 mmol/L, 95% CI -0.45 to 0.32, $I^2 = 0\%$, 148 participants, 2 RCTs, Analysis 4.11), while only one of the trials reported on total cholesterol at one year (MD -0.16 mmol/L, 95% CI -0.51 to 0.19, 99 participants, 1 RCT, Analysis 4.10).

Average changes in LDL cholesterol over one year to 18 months in the two trials ranged from reductions of 0.2 mmol/L to 0.05 mmol/L with low-carbohydrate diets and from a reduction of 0.17 mmol/L to an increase of 0.04 mmol/L with balanced-carbohydrate diets. For HDL cholesterol, average increases over this period ranged from 0.04 mmol/L to 0.08 mmol/L with low-carbohydrate weight-reducing diets and from 0.03 mmol/L to 0.08 mmol/L with balanced-carbohydrate weight-reducing diets. Average changes in total cholesterol at one year reported by the single study ranged from a reduction of 0.15 mmol/L in the low-carbohydrate group to an increase of 0.01 mmol/L in the balanced-carbohydrate group. For triglycerides, average changes over one year to 18 months in the two trials ranged from a reduction of 0.47 mmol/L to an increase of 0.07 mmol/L with low-carbohydrate diets and from reductions of 0.3 mmol/L to 0.05 mmol/L with balanced-carbohydrate diets.

Participant-reported adverse effects

Two adverse effects were reported by a single trial in comparison 4 (Watson 2016). This trial reported on **anxiety** at six months using the 'Anxiety and worry' subscale of the D-39 diabetes QoL questionnaire, but did not report sample sizes per group. The mean score in the low-carbohydrate diet group was 33.91 (SE 3.55) and in the balanced diet group was 31.43 (SE 3.71). **Fatigue** at six months was also reported on by this trial using the 'Energy and mobility' subscale of the D-39 diabetes QoL questionnaire. The mean score in the low-carbohydrate diet group was 22.04 (SE 2.49) and in the balanced diet group was 23.28 (SE 2.61), with no sample sizes being reported per group.

DISCUSSION

Summary of main results

This review examined the effects of low-carbohydrate weight-reducing diets compared to 'balanced'-carbohydrate weight-

reducing diets on weight and cardiovascular risk factors. We used approaches aimed at addressing factors that may limit interpretation in other similar reviews. These included explicit criteria for the compositions and intentions of the treatment and control diets, stratifying findings in participants without and with T2DM, separating findings from weight-reducing and weight-maintenance phases of diets, meaningful and comparable follow-up periods, comprehensive searches, and multiple efforts to obtain and include all relevant and necessary data and information not reported in published papers; as well as assessing the certainty of this evidence using GRADE. To our knowledge, this review includes the largest number of trials that have examined this question to date.

Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets (weight-reducing phases only)

Participants without and with T2DM in both low-carbohydrate and balanced-carbohydrate diet groups reduced their weight to varying degrees in the short term (range of weight reduction across both diets: 12.2 to 0.33 kg) and long term (range of weight reduction across both diets: 13.1 to 1.7 kg). We considered a loss of at least 5% of initial weight to be clinically meaningful, and a weight change that could reasonably be expected in our minimum diet duration of 12 weeks. Thus, reductions from around the middle of these ranges (about 4 to 6 kg in most trials) would start to become clinically meaningful and translate to improvements in cardio metabolic health (Brown 2016; Franz 2015; Jensen 2014; Truby 2006; Wald 2012; Wing 2010).

Notably, in overweight and obese participants without and with T2DM, the meta-analyses showed little or no difference between the effects of low-carbohydrate weight-reducing diets and balanced-carbohydrate weight-reducing diets on weight reduction over three to 8.5 months (short term), with mean differences in weight reduction of about one kilogram. This was also the case over one to two years (long term), with mean differences in weight reduction of less than one kilogram. The 95% CIs of pooled mean differences in short- and long-term weight change did not include appreciable harm or benefit (ranging from 2.44 kg lower to 1.46 kg higher), and we therefore did not downgrade for imprecision. The lack of differences found in effects on weight reduction were confirmed by sensitivity analyses. There was, however, some heterogeneity in effects in participants without T2DM over the short term. Subgrouping by similarity of energy prescription, extent of carbohydrate restriction, diagnosed cardiovascular event or disease at baseline or gender did not suggest important clinical differences in average effects between the various subgroups. Mean differences in weight reduction between diet groups across the various subgroups at the short term ranged between 0.25 kg and 2.71 kg. Some heterogeneity could be explained by subgrouping studies according to similarity of energy prescription and extent of carbohydrate restriction.

We do not know whether there is a difference in the number of participants per group with weight loss of at least 5% at the long term since only one trial ($n = 68$) in men, judged as being at high risk of bias, reported on this outcome.

For mean changes in DBP at one to two years, some trials reported reductions and other trials reported increases in both diet groups in participants without and with T2DM (range of mean change across

diet groups: -11 to 4.3 mmHg). In all participants, meta-analyses showed little or no difference between the effects of the two diets on changes in DBP at one to two years, with mean differences of less than 0.5 mmHg. The 95% CIs of these pooled mean differences did not include appreciable harm or benefit (ranging from 1.84 mmHg lower to 1.28 mmHg higher) and we did not downgrade for imprecision. We considered changes in DBP of greater than 2 mmHg to be clinically meaningful (Whelton 2002).

At one to two years in both diet groups, some trials reported reductions in LDL cholesterol and others reported increases in participants without and with T2DM (range of mean change across diet groups: -0.61 to 0.6 mmol/L). Meta-analyses showed little or no difference between the effects of the two diets on changes in LDL cholesterol at one to two years in all participants, with mean differences of up to 0.1 mmol/L. The 95% CIs of these pooled mean differences did not include appreciable harm or benefit (ranging from 0.05 mmol/L lower to 0.26 mmol/L higher) and we did not downgrade for imprecision. We considered changes in LDL cholesterol of greater than 0.26 mmol/L to be clinically meaningful (Fernandez-Friera 2017; Howard 2000).

At one to two years, some trials in participants with T2DM reported reductions in HbA1c and others reported small increases in HbA1c in both diet groups (range of change across diet groups: -2% to 0.2%). Pooling these mean differences found little or no difference between the effects of low-carbohydrate weight-reducing diets versus balanced-carbohydrate weight-reducing diets on change in HbA1c over one to two years in overweight and obese participants with T2DM, with a mean difference of 0.14%. The 95% CI of the pooled mean difference did not include appreciable harm or benefit (0.38% lower to 0.1% higher) and we did not downgrade for imprecision. We considered changes in HbA1c of greater than 0.5% to be clinically meaningful (NICE 2015).

Participant-reported adverse effects were poorly reported. In the few trials where these were reported, the effects included constipation, which we regarded as a patient-important adverse effect since it is frequently reported by people following low-carbohydrate diets. These limited data mean that we are very uncertain about whether there is a difference in the number of participants per diet group with constipation at three to six months in all participants.

Low-carbohydrate weight-reducing diets compared to balanced-carbohydrate weight-reducing diets (weight-reducing phase followed by weight-maintenance phase)

Evidence about the comparative effects of diets from studies using weight-reducing phases followed by weight-maintenance phases was limited. Only eight trials reported these data for some outcomes, and one of these trials did not contribute any numeric data to meta-analyses. All the trials applied different approaches and time frames to the weight-maintenance phases of the diets, with the shortest weight-maintenance phase being six weeks and the longest being 21 months. Findings were similar to the comparisons that included only weight-reducing phases of the two diets, but our certainty in these findings was lower, largely due to imprecision, with small total sample sizes and wide 95% CIs around the pooled estimates.

In overweight and obese participants without T2DM, meta-analyses showed that low-carbohydrate weight-reducing diets

including a weight-maintenance phase may result in little or no difference in change in weight over one to two years compared to balanced-carbohydrate weight-reducing diets including a weight-maintenance phase. We are very uncertain about whether there are differences in effects on DBP and LDL cholesterol between the two diets in these participants. None of the eight trials reported usable data for the other outcomes in our summary of findings table.

In overweight and obese participants with T2DM, meta-analyses showed that low-carbohydrate weight-reducing diets including a weight-maintenance phase may result in little or no difference in change in weight at six months, and at one to two years, compared to balanced-carbohydrate weight-reducing diets including a weight-maintenance phase. This was also the case for change in HbA1c and LDL cholesterol. We are very uncertain about whether there are differences in effects on DBP between the two diets in these participants. None of the eight trials reported usable data for the other outcomes in our summary of findings table.

Overall completeness and applicability of evidence

Our review employed a comprehensive search strategy with no language restrictions to identify all RCTs assessing the effects of low-carbohydrate weight-reducing diets on weight and cardiovascular risk in overweight and obese adults without or with T2DM. We tapped multiple sources of information for all trials and contacted study authors multiple times in all cases where we needed additional data or information. This included requesting information from 30 author teams to enable clear judgements and reporting related to eligibility, stratification, risk of bias, as well as numeric data to enable the inclusion of as much usable data in meta-analyses as we could obtain.

We prespecified outcomes at defined lengths of follow-up to examine possible differences in effects over time. No trials reported on outcomes after two years, and 60% of trials had a duration of six months or less. Change in body weight was reported by most trials, but few studies reported on the number of participants per group with weight loss of at least 5% from baseline. Despite multiple attempts, we were not able to obtain and include weight change data from 11 trials, as they reported data in unusable formats.

None of the trials reported on all-cause mortality, cardiovascular mortality, non-fatal myocardial infarction, non-fatal stroke and diagnosis of T2DM. This is to be expected to some degree in view of the practical challenges posed by long durations of follow-up in weight-reducing diet trials. Pooled data from long-term prospective cohort studies on dietary carbohydrate intake and mortality have demonstrated harm at the extremes of intake (Seidemann 2018). Moreover, a range of potential shorter- and longer-term safety concerns of low-carbohydrate diets have been discussed in recent papers, such as reduced dietary intake of fibre, minerals, vitamins, trace elements and polyunsaturated fats, unknown effects of long-term ketosis, harmful environmental impacts and dysbiosis (Barber 2021; Sievenpiper 2020).

The effect of weight reduction per se on cardiovascular risk factors is also important for interpreting this evidence, as it is known that a weight reduction of 5% or more is associated with improvements in cardio metabolic risks, including blood lipids, blood pressure and HbA1c (Brown 2016; Franz 2015). As we found little to no difference in weight reduction between low-carbohydrate and balanced-

carbohydrate diets up to two years, one would reasonably not expect to find meaningful differences in effects on blood lipids, blood pressure and HbA1c between the two diets, which was the case in our review.

Our review did not seek to address effects of differences in the quality of dietary carbohydrates, or the quality of the replacement macronutrients (e.g. fat). Both quality and quantity or proportions are vital components of understanding the effects of macronutrients on health outcomes (Abdelhamid 2018; Barber 2021; Hooper 2020; Reynolds 2019; Sievenpiper 2020).

A criticism of examining mean differences in weight between diet groups is that they do not fully account for true different individual responses, where 'true' refers to individual response differences that are not a result of random trial-to-trial variability. In the context of 'personalised' nutrition, there is interest in ascertaining whether there are true individual differences in the responses to weight-reducing diets large enough to be clinically relevant. A recent systematic review, using a response variance comparison approach, examined whether the weight responses to low-carbohydrate diets or low-fat diets (typically, balanced-carbohydrate diets) differ between individuals, and was unable to detect clinically relevant differences in individual response heterogeneity between the two diets (Smith 2020).

All except one of the 61 trials were conducted in high-income countries. There are, however, no obvious reasons to expect the effects of low-carbohydrate weight-reducing diets on body weight to be different in people from low- and middle-income countries. High costs of low-carbohydrate diets and disproportionate financial effects on lower socioeconomic groups, which are beyond the scope of our review, have been covered elsewhere (Barber 2021; Raffensperger 2008).

Nearly 40% of included trials reported some or all funding by food/diet industry and related private companies, such as food and nutrition product manufacturers, organisations representing the interests of food producers (e.g. Pork Council, Dairy Farmers Association) and diet book and diet product organisations.

There are many individual and environmental factors that influence a person's ability to adhere to weight-reducing diets, and studies have shown that adherence to weight-reducing diets is one of the major factors that determine success over the short and long term (Gibson 2017). Systematic reviews and RCTs of low- and balanced-carbohydrate weight-reducing diets have demonstrated that adherence is a problem, and reduces over time with both diets, with some of these specifically reporting difficulty with adhering to severely carbohydrate-restricted diets over the long term (Foster 2003; Gibson 2017; Ross 2021; Sacks 2009). We did not investigate the possible influence of adherence on the effects of the dietary interventions. However, we did extract information on fidelity for both diets (Characteristics of included studies), i.e. the degree to which an intervention happened in the way the investigators intended it to (Hoffman 2014).

Quality of the evidence

The interpretation of most weight reduction trials is constrained by small samples, a lack of blinding, and large loss to follow-up (Simons-Morton 2006), which were also observed across the trials in our review. None of the trials in the review were judged as having

low risk of bias overall. The overall risk of bias of outcomes across trials in participants without and with T2DM was predominantly high, largely due to high proportions of missing outcome data in many trials.

Potential biases in the review process

The review may be affected by non-reporting bias. For the 'known unknowns' (particular results from a trial not reported in a usable format), we contacted trial authors multiple times to obtain the data in a usable format. Failure to obtain this and consequent exclusion thereof is a limitation of the review process, as we cannot be absolutely certain if and how the inclusion of these data would have affected the pooled estimates. However, given the agreement in pooled mean differences in weight reduction between our review and other similar reviews, we think it is unlikely that these data would have meaningfully changed our pooled estimates. It was harder to make a judgement about the 'unknown unknowns' (entire eligible trials not reported or picked up by our comprehensive searching), but it is possible that small unpublished trials are missing. Interpreting funnel plot asymmetry was challenging since many trials had similar standard errors.

We excluded RCTs of less than 12 weeks' duration which may have been relevant to the review question. The reason for choosing only trials with at least 12 weeks follow-up was to allow sufficient time to detect clinically meaningful weight and cardiovascular risk factor changes.

Agreements and disagreements with other studies or reviews

Pooled mean differences in weight reduction and cardiovascular risk factors in our review are in line with a number of recent systematic reviews with pairwise meta-analyses (Chawla 2020; Dong 2020; Smith 2020; Yang 2021), and an older review with network meta-analyses (Johnston 2014), in participants without T2DM. This is also the case for recent similar reviews in participants with T2DM (Meng 2017; Silverii 2020; Snorgaard 2017; Van Zuuren 2018). Systematic reviews with varying definitions of low-carbohydrate diets and differing eligibility criteria have shown that low-carbohydrate diets do not result in superior long-term clinically meaningful weight reduction. An overview of systematic reviews of RCTs comparing low-carbohydrate to control diets (low-fat or energy-restricted) in adults with overweight and obesity included 12 reviews (10 with meta-analyses) and reported an inverse relationship between number of trial participants and the size of differences in weight loss (Churuangasuk 2018).

AUTHORS' CONCLUSIONS

Implications for practice

The small pooled mean differences in weight reduction between the diets (about 1 to 2 kg), while statistically significant in the short term, were not clinically important in the short or long term in an overweight and obese adult, without or with T2DM (low-to moderate-certainty evidence). These differences are similar to typical ranges of biological weight fluctuations over time (Liska 2019; Vuorinen 2021), and can at least in part be ascribed to biological weight fluctuations, which are influenced by various factors including level of activity, hydration status, season and medications. When interpreting the sizes of the mean differences of weight reduction between the two diets, one should also

consider the total body water loss (2 to 3 kg) that follows dietary carbohydrate restriction due to diet-induced diuresis from glycogen depletion and production of ketone bodies, which is restored when carbohydrates are eaten again (Denke 2001; Yang 1976).

Our systematic review failed to show that low-carbohydrate weight-reducing diets are superior to balanced-carbohydrate weight-reducing diets, with little or no difference in weight reduction and cardiovascular risk factors over the short (three to 8.5 months) and long term (one to two years). Trials did not report on our prespecified outcomes after two years of follow-up. The range of potential safety concerns of low-carbohydrate diets not addressed in this review over the short and longer term should also be considered.

Most trials included participants without diagnosed cardiovascular disease or events at baseline, and average baseline LDL cholesterol concentrations and DBP across the trials were within the normal ranges defined for people without coronary artery disease. In people with lipid disorders and variability with atherogenic lipoprotein response, caution in recommending low-carbohydrate and consequent high-fat diets is warranted. Evidence on participant-reported adverse effects over two years was limited and we could not draw any conclusions about these.

Dietary modification is central to weight reduction, however, in view of the complex aetiology of obesity, it is important to consider the demonstrated value of combining diet and other positive lifestyle and behavioural interventions to reduce weight and cardiovascular risk. Current dietary guidance allows for flexibility in the proportion of macronutrients, including a wide range of carbohydrate intakes, with greater emphasis on quality over quantity and on total dietary patterns over single nutrients.

Implications for research

In view of the challenges associated with weight-reducing diet trials and the similar findings from this and other comparable reviews, it could reasonably be argued that additional trials on this question are not needed. However, the effects of low-carbohydrate diets

compared to balanced-carbohydrate diets beyond two years is unknown. If conducted, future trials on this question in participants without and with T2DM, should be longer than two years, adequately powered with greater attention to methodological quality, and specifically the use of more appropriate and rigorous statistical approaches to address loss to follow-up, where relevant. Prospective registration, publication of protocols and of detailed data analysis plans, as well as use of appropriate reporting guidelines (e.g. CONSORT) by future trials, would also be beneficial to the quality and utility of any future research. Other key research areas related to dietary interventions for weight-reduction and cardiovascular health include improving dietary adherence, which is critical to both short- and long-term weight loss, total dietary patterns and macronutrient quality.

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet, restricted in control diet

Treatment diet:

Name (as reported) and brief description: Modified low-carbohydrate diet, first phase (two weeks) higher intake of fat (62%), very low intake of carbohydrates (10%) and protein intake of 28%. In the second phase (two weeks) intakes were adjusted to 43% fat, 27% carbohydrate and 30% protein. In the third phase (eight weeks) 39% fat, 28% carbohydrates and 33% protein. In the maintenance phase, approximate calories consumed based on the recommended guidelines were also about 1300 for women and 1600 for men.

Treatment diet type (carbohydrate-fat-protein): Very low2w to low10w-high-high

Exercise component? No

Recipients: N = 14 women and N = 15 men with mean (SD) age 46 (10) years, mean (SD) weight 99.1 (31.9) kg, mean (SD) BMI 34.9 (4.0) kg/m², mean(SD) total cholesterol 212.9 (46.2) mg/dL, mean (SD) LDL 128.3 (44.8) mg/dL, mean (SD) HDL 50.3 (14.3) mg/dL, mean (SD) triglycerides 181.3 (134.0) mg/dL, N = 13 (44.8%) had hypertension, N = 2 (6.9%) had had a myocardial infarction, N = 0 had congestive heart failure, N = 0 had had a stroke, N = 2 (6.9%) had diabetes and N = 2 (6.9%) were smokers.

Why? Isocaloric diet lower in carbohydrates and higher in protein and monounsaturated fat would have a more favorable effect on weight loss and reduce cardiovascular risk factors.

What (materials)? Written diet guidelines

What (procedures)? The MLC diet consisted of 2 phases of 2 weeks' duration and of a third or maintenance phase of 8 weeks. The first phase was characterised by higher intake of fat (62%), very low intake of carbohydrates (10%), and an intake of protein of 28%. In the second phase, fat intake was decreased to 43% whereas carbohydrate intake was increased to 27% and protein intake to 30%. In the third phase, the percentages of calories were 39% from fat, 28% from carbohydrates, and 33% from protein. Sessions with the dietitian/nurse for 1 hr at baseline and 30 mins at subsequent visits with 24-hr food recall being asked. Lipid profiles were done at baseline and final visit.

Who provided? "A single specially trained dietitian and nurse practitioner instructed participants about their assigned diet..."

How and where? Face-to-face at the Mount Sinai Medical Center–Miami Heart Institute

When and how much? "All participants, regardless of their assignment, met with the dietitian or the nurse practitioner for 1 hour at the first visit and 30 minutes at subsequent visits, every two weeks for 12 weeks."

Strategies to improve or maintain fidelity; tailoring and modification: "To assess the appropriateness of the foods consumed, 24-hour food recalls were obtained. Because the goal of the 24-hour food recalls was to provide feedback to the participants, the information was insufficient to perform any quantitative analysis."

Extent of intervention fidelity: NR

Concomitant interventions: N = 2 (6.9%) were on lipid lowering drugs.

Control diet:

Aude 2004 (Continued)

Name (as reported) and brief description: US National Cholesterol Education Program (NCEP) diet, 30% of calories from fat, 55% from carbohydrates and 15% from protein. Saturated fat < 7% of total fat, MUFA between 10 and 15%. Diet tailored to provide approximately 1300 calories for women and 1600 calories for men.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 14 women and N = 11 men with mean (SD) age 44 (10) years, mean (SD) weight 99.9 (21.1) kg, mean (SD) BMI 35.5 (6.0) kg/m², mean(SD) total cholesterol 205.8 (36.5) mg/dL, mean (SD) LDL 122.4 (26.7) mg/dL, mean (SD) HDL 54.3 (18.6) mg/dL, mean (SD) triglycerides 145.6 (80) mg/dL, N = 7 (28.0%) had hypertension, N = 0 had had a myocardial infarction, N = 0 had congestive heart failure, N = 0 had had a stroke, N = 0 had diabetes and N = 2 (8.0%) were smokers.

Why? NCEP diets increase the risk of cardiovascular events due to rise in triglycerides and reduction in HDL.

What (materials)? Written diet guidelines

What (procedures)? In the NCEP diet the percentages of calories from fat (30%), carbohydrate (55%), and protein (15%) were unchanged throughout the trial. Saturated fat comprised less than 7% of the total fat intake, and monounsaturated fat between 10% and 15%. The diet was tailored to provide approximately 1300 calories for women and 1600 calories for men.

Who provided? "A single specially trained dietitian and nurse practitioner instructed participants about their assigned diet..."

How and where? Face-to-face at the Mount Sinai Medical Center–Miami Heart Institute

When and how much? "All participants, regardless of their assignment, met with the dietitian or the nurse practitioner for 1 hour at the first visit and 30 minutes at subsequent visits, every two weeks for 12 weeks."

Strategies to improve or maintain fidelity; tailoring and modification: "To assess the appropriateness of the foods consumed, 24-hour food recalls were obtained. Because the goal of the 24-hour food recalls was to provide feedback to the participants, the information was insufficient to perform any quantitative analysis."

Extent of intervention fidelity: NR

Concomitant interventions: N = 0 were on lipid lowering drugs.

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: No

Change in BMI (kg/m²) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: No

Change in SBP (mmHg) at ≥ 12 months: No

All-cause mortality at ≥ 12 months: No

Aude 2004 (Continued)

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥ 12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: No

Change in LDL (mmol/L) at ≥ 12 months: No

Change in HDL (mmol/L) at ≥ 12 months: No

Change in non-HDL (mmol/L) at ≥ 12 months: No

Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: No

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: No

Participant-reported adverse effects: No

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein weight loss (HP-WL) diet prescribing 1.2 g/kg body weight of protein with a target of 30 g protein/meal and a distribution of ~30% protein, 30% fat and 40% carbohydrates. Energy intake ~500 kcal below calculated requirement

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: N = 51 women, mean (SD) age 58.9 (8.4) and range 45.0–78.0 years, mean (SD) weight 98.6 (18.6) kg, mean (SD) BMI 37.5 (6.1) kg/m² and mean (SD) fasting blood glucose 111.7 (40.9) mg/dL

Why? To evaluate the effects of a high protein diet with balanced protein distribution on lean muscle mass for weight loss and preserving physical function

What (materials)? "Participants received individualized kilocalorie prescription and meal plans. To promote achievement of the protein intake target, participants were supplied with preportioned frozen or chilled lean meats (lean ground pork, pork tenderloins, pork chops, and low-sodium ham) sufficient to provide \$420 g protein/wk (\$30 g for 2 meals/d) for the duration of the trial."

What (procedures)? HP-WL participants were prescribed a protein intake of 1.2 g/kg body weight, with a target of 30 g protein/meal and a distribution of 30% protein, 30% fat, and 40% carbohydrates. Because high-quality protein is superior for promoting anabolism (29, 30), the HP-WL meal plan emphasised protein from animal sources, primarily lean meats and poultry, low-fat dairy, fish, and eggs. To avoid monotony and allow flexibility, participants consumed other complete proteins (e.g. other lean meats, poultry and fish, low-fat dairy foods, and eggs) at the third meal of each day according to their prescribed meal plan. All of the participants were prescribed an energy intake; 500 kcal below their calculated requirement, as derived from calculations of estimated total energy expenditure on the basis of weight, height, sex, age, and activity level with the use of published equations. Meetings with the dietitian (individual and group) with diet plans provided and assessments of nutrient intakes made per protocol

Who provided? "Registered dietitians who were experienced in obesity treatment..."

How and where? Face-to-face at Duke University Medical Center facilities

When and how much? "After the 2 individual sessions, participants attended weekly group meetings (specific to study group but equivalent in structure and duration) for diet and health-related counseling, peer support, and weekly weigh-ins."

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

Bales 2017 (Continued)

Strategies to improve or maintain fidelity; tailoring and modification: "Interventionists reviewed participants' daily food journals each week and adjusted their menus to ensure that the target kilocalorie intake and, for the HP-WL group, 30 g protein/meal for breakfast, lunch, and dinner were regularly achieved, as previously described." Weigh-ins and group meetings were also conducted.

Extent of intervention fidelity: Weekly sessions and assessments. To promote achievement of the protein intake target, participants were supplied with preportioned frozen or chilled lean meats during the whole trial.

Concomitant interventions: "All participants were supplied with a low-dose multivitamin supplement (GNC Teen Multivitamin), along with 400 mg Ca and 600 IU vitamin D (Bayer Citracal Calcium Supplement +D3) to ensure adequate nutrient intake and to standardize supplement use (participants were instructed to discontinue all other nutritional supplements)."

Control diet:

Name (as reported) and brief description: Control weight loss (C-WL) diet prescribing RDA for protein of 0.8 g/kg body weight with a distribution of calories of ~15% protein, 30% fat and 55% carbohydrates. Energy intake ~500 kcal below calculated requirement

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 29 women, mean (SD) age 61.8 (7.6) and range 46.0–73.0 years, mean (SD) weight 103.0 (15.6) kg, mean (SD) BMI 38.3 (5.8) kg/m² and mean (SD) fasting blood glucose 106.9 (31.2) mg/dL

Why? NR

What (materials)? "Participants received individualized kilocalorie prescription and meal plans."

What (procedures)? The C-WL group was prescribed the RDA for protein of 0.8 g/kg body weight, with a distribution of calories of 15% protein, 30% fat, and 55% carbohydrates. All of the participants were prescribed an energy intake 500 kcal below their calculated requirement, as derived from calculations of estimated total energy expenditure on the basis of weight, height, sex, age, and activity level with the use of published equations. Meetings with the dietitian (individual and group) with diet plans provided and assessments of nutrient intakes made per protocol

Who provided? "Registered dietitians who were experienced in obesity treatment..."

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No
Number of participants with 5% weight loss from baseline at ≥ 12 months: No
Change in BMI (kg/m²) at 3 to 12 months: No
Change in BMI (kg/m²) at ≥ 12 months: No
Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No
Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No
Change in DBP (mmHg) at ≥ 12 months: No
Change in SBP (mmHg) at ≥ 12 months: No
All-cause mortality at ≥ 12 months: No
Cardiovascular mortality at ≥ 12 months: No
Non-fatal myocardial infarction at ≥ 12 months: No
Non-fatal stroke at ≥ 12 months: No
Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No
Change in HbA1c (%) at ≥ 12 months: No
Change in LDL (mmol/L) at ≥ 12 months: No
Change in HDL (mmol/L) at ≥ 12 months: No
Change in non-HDL (mmol/L) at ≥ 12 months: No
Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: No
Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: No
Participant-reported adverse effects: No

Notes

Number and type of records(s): journal article

Trial acronym/name: POWR-UP

Trial funded by: Pork Checkoff Program, North Carolina Pork Council, Smithfield Foods and the NIH (grants 5T32 AG000029, 1P30 AG028716 and K12 HD043446)

Declaration of interest: "Author disclosures: CW Bales, KN Porter Starr, MC Orenduff, SR McDonald, K Molnar, AK Jarman, A Onyenwoke, H Mulder, ME Payne, and CF Pieper, no conflicts of interest. The sponsors had no influence on the protocol design, conduct of the trial, or data analysis."

Bazzano 2014
Study characteristics

Methods

Review comparison(s) addressed by this study: 1

Study design: RCT, parallel, single-centre (1)

Trial registry number: NCT00609271

Total number of trial arms: 2

Bazzano 2014 (Continued)

Year trial started: 2008

Sample size calculation: yes

Outcome(s) used for sample size calculation: weight change

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 52 weeks

What was the duration of the weight maintenance phase: NA

Other notes about methods: NA

Participants

Country and setting: USA, outpatient university health sciences centre in New Orleans. One low-carbohydrate or low-fat meal replacement (bar or shake) per day was provided.

Eligibility criteria: Participants aged 22 to 75 years with a BMI 30 to 45 kg/m². Participants were excluded if they had self-reported cardiovascular disease, type 2 diabetes or kidney disease; used pre-prescription medication for weight loss; had surgery or weight loss of more than 6.8 kg in the past six months.

Type 2 diabetes at baseline: No

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Mixed

Total number randomised: 148

Total attrition in trial: 29

Treatment diet

Participants randomised: 75

Participants withdrawn (voluntary): NR

Total attrition: 16

Control diet:

Participants randomised: 73

Participants withdrawn (voluntary): NR

Total attrition: 13

Baseline data treatment diet:

Randomised participants not included: None

Age (years): mean (SD) 45.8 (9.9)

Gender distribution (as reported): female 66/75 (88%), male 9/75 (12%)

Weight (kg): mean (SD) 96.3 (12.7)

BMI (kg/m²): mean (SD) 35.2 (3.8)

DBP (mmHg): mean (SD) 77.5 (9.0)

SBP (mmHg): mean (SD) 120.3 (12.8)

HbA1c (%): NR

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.3 (1.1)

TG (mmol/L): mean (SD) 1.4 (0.9)

Group differences at baseline: no

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Unrestricted/ad libitum prescription in both diets

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate diet. Participants assigned to the low-carbohydrate diet were instructed to maintain intake of digestible carbohydrate (total carbohydrate minus total fiber) of less than 40 g/d. Diet did not include a specific calorie or energy goal.

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? No

Recipients: N = 75 of which N = 66 (88%) female, mean (SD) age 45.8 (9.9) years, mean (SD) weight 96.3 (12.7) kg, mean (SD) BMI 35.2 (3.8) kg/m², mean (SD) waist circumference 108.4 (9.3) cm, mean (SD) systolic BP 120.3 (12.8) mmHg, mean (SD) diastolic BP 77.5 (9.0) mmHg, mean (SD) total cholesterol 5.1 (1.1) mmol/L, mean (SD) LDL 3.2(0.9) mmol/L, mean (SD) HDL 1.4 (0.3) mmol/L, mean (SD) triglycerides 1.3 (0.6) mmol/L, mean (SD) plasma glucose 5.2 (0.6) mmol/L.

Why? "Few randomized, controlled trials thus far have examined the effects of carbohydrate restriction on CVD risk factors in a diverse population with a significant proportion of black persons."

Bazzano 2014 (Continued)

What (materials)? "A handbook was given to participants that contained recipes, sample menus for 1 week of food intake at various energy levels, food lists, shopping lists, meal planners, and guides on counting macronutrients and reading nutrition labels. We also provided 1 low-carbohydrate or low-fat meal replacement (bar or shake) per day to participants in each group for the duration of the study."

What (procedures)? Participants assigned to the low-carbohydrate diet were instructed to maintain an intake of digestible carbohydrate (total carbohydrate minus total fiber) of less than 40 g/d. Dietary advice as per the "National Cholesterol Education Program guidelines". Neither diet included a specific calorie or energy goal. Participants in each group were asked to refrain from changing their physical activity levels during the intervention. Meetings were conducted with the dietitian weekly then monthly for the study period; these meetings were initially individualised and then group wise. Dietary recalls were also conducted to reflection on consumption over weekday and weekend.

Who provided? Dietitian conducted the counselling sessions and all dietary recalls were obtained by a trained and certified staff member.

How and where? Face-to-face at the Tulane University Health Sciences Center in New Orleans, Louisiana

When and how much? "Participants met with a dietitian in weekly individual counseling sessions for the first 4 weeks, followed by small group counseling sessions every other week for the next 5 months (a total of 10 sessions) and monthly for the last 6 months of the intervention period. Individual sessions generally lasted about 1 hour and included dietary instruction and supportive counseling. Group counseling sessions were held separately for participants in the low-fat and low-carbohydrate groups but followed a common behavioral curriculum."

Strategies to improve or maintain fidelity; tailoring and modification: Trained and certified staff, single calibrated scales, standard procedures for all

Extent of intervention fidelity: NR

Concomitant interventions: N = 21 (28%) on antihypertensive meds, N = 12 (16%) were on lipid-lowering meds.

Control diet:

Name (as reported) and brief description: Low-fat diet. Those assigned to the low-fat diet were instructed to maintain less than 30% of their daily energy intake from total fat (with < 7% saturated fat) and 55% from carbohydrate. Diet did not include a specific calorie or energy goal.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 73 of which N = 65 (89%) female, mean (SD) age 47.8 (10.4) years, mean (SD) weight 97.9 (13.4) kg, mean (SD) BMI 35.6 (4.5) kg/m², mean (SD) waist circumference 111.0 (10.7) cm, mean (SD) systolic BP 124.9 (13.8) mmHg, mean (SD) diastolic BP 79.4 (8.3) mmHg, mean (SD) total cholesterol 5.3 (1.1) mmol/L, mean (SD) LDL 3.2 (1.0) mmol/L, mean (SD) HDL 1.5 (0.3) mmol/L, mean (SD) triglycerides 1.4 (0.9) mmol/L, mean (SD) plasma glucose 5.2 (0.5) mmol/L

Why? NR

Benassi-Evans 2009 (Continued)

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein high red meat (HP) diet. Consisted of 35% protein, 40% carbohydrate and 25% fat. Total energy content was 7000 kJ.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: Men only N = 16, mean (SE) age 54.94 (1.17) years, mean (SE) weight 99.84 (2.45) kg, mean (SE) BMI 32.42 (0.79) kg/m².

Why? "...we anticipated that the expected increased intake in the HP diet of folate, vitamin B12, niacin, vitamin E and calcium might result in lower peripheral blood lymphocytes (PBL), MN frequency given that higher intake of these vitamins is associated with lower MN frequency in PBLs in previous studies."

What (materials)? Food checklists

What (procedures)? Participants were prescribed a high protein–high red meat (HP) diet (35% protein, 40% carbohydrate, 25% fat). The total energy content of both diets was 7000 kJ, with some adjustments in energy (while maintaining protein to energy ratios) necessary for individuals to achieve an approximate weight loss of 1 kg per week. Twelve-week intensive weight loss phase and 1 year maintenance phase continuing with the same diet strategy that the participant consumed in the 1st 12 weeks. Dietitian consultations were provided over the whole 1 year period with checklists being issued every 4 weeks.

Who provided? Dietitian

How and where? Face-to-face individual consultations, location NR

When and how much? Fortnightly clinic visits during weight loss phase (12 weeks), thereafter monthly during weight maintenance phase (until 1 year)

Strategies to improve or maintain fidelity; tailoring and modification: Dietary intake for 6 days/month was analysed from the checklists using FoodWorks dietary analysis package.

Extent of intervention fidelity: The HP-diet group recorded a significantly greater intake of protein, folate and iron at both weeks 12 and 52. Fibre and calcium intake was significantly higher in the HP group at week 12 only, while total fat intake was recorded as significantly higher in the HP group for week 52 only.

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: High-carbohydrate low red meat (HC) diet. Consisted of 17% protein, 58% carbohydrate and 25% fat. Total energy content was 7000 kJ.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Men only N = 17, mean (SE) age 52.94 (1.50) years, mean (SE) weight 99.58 (3.61) kg, mean (SE) BMI 31.47 (0.96) kg/m².

Why? NR

What (materials)? Food checklists

What (procedures)? Participants were prescribed a high carbohydrate–low red meat (HC) diet (17% protein, 58% carbohydrate, 25% fat). The total energy content of both diets was 7000 kJ, with some ad-

Benassi-Evans 2009 (Continued)

justments in energy (while maintaining protein to energy ratios) necessary for individuals to achieve an approximate weight loss of 1 kg per week.

Brehm 2003 (Continued)

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Very low carbohydrate diet, dieters instructed to follow an ad libitum diet with a maximum intake of 20 g/d carbohydrate to induce ketosis. After 2 weeks subjects were permitted to increase their intake of carbohydrates to 40-60 g/d only if testing of urinary ketones continued to indicate ketosis.

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? No

Recipients: 22 women with mean (SD) age 44.22 (6.84) years, mean (SD) weight 91.20 (8.4) kg's, mean (SD) BMI 33.17 (1.83) kg/m², mean (SD) systolic BP 116 (3.23) mmHg, mean (SD) diastolic BP 79 (2.69) mmHg, mean (SD) total cholesterol 206.32 (6.63) mg/dL, mean (SD) triglycerides 148.73 (13.41) mg/dL, mean (SD) LDL 124.86 (5.39) mg/dL, mean (SD) HDL 51.77 (2.82) mg/dL, mean (SD) glucose 99.1 (2.6) mg/dL

Why? "Increased consumption of fat, particularly saturated fat, has been linked to increased plasma concentrations of lipids, insulin resistance, glucose intolerance, and obesity. Therefore, it is possible that many Americans could actually suffer adverse health effects by using very low carbohydrate diets in an attempt to lose weight."

What (materials)? Self-testing kits for ketosis, cooking tips, food diaries and pedometers (worn for 3 days a week). No specific exercise routine

What (procedures)? Participants were instructed to follow an ad libitum diet with a maximum intake of 20 g carbohydrate. It was anticipated that this diet would induce ketosis. After 2 wk of dieting, subjects were permitted to increase their intake of carbohydrate to 40-60 g/d only if self-testing of urinary ketones continued to indicate ketosis. Group meetings addressed cooking tips, stress management, behaviour modification, and relapse prevention. On alternating weeks, individual counselling sessions took place where the dietitian reviewed their 3-d food records from the previous week and provided dietary recommendations and positive reinforcement. Subjects were advised to continue their baseline level of activity. At the end of the 3-month intervention, subjects were instructed to continue with their weight loss efforts, but without scheduled contact with the dietitians until the 6-month assessment.

Who provided? Dietitians provided the intervention and the research nurses did the assessments.

How and where? Face-to-face on the University of Cincinnati campus

When and how much? Two registered dietitians delivered a 3-month intervention aimed at promoting dietary compliance. Group meetings with subjects on the same diet were held biweekly. On alternating weeks, subjects met for individual counselling session.

Strategies to improve or maintain fidelity; tailoring and modification: "On alternating weeks, subjects met for individual counseling session during which their assigned dietitian reviewed their 3-d food records from the previous week, analyzed by Nutritionist V (First Data Bank, San Bruno, CA), and provided dietary recommendations and positive reinforcement."

Extent of intervention fidelity: At 3 months the caloric intake in the very low carbohydrate diet group was distributed as 15% carbohydrate, 28% protein, and 57% fat. At 3 months, the very low carbohydrate diet group consumed significantly less carbohydrate, vitamin C, and fiber and significantly more protein, total fat, saturated fat, monounsaturated fat, polyunsaturated fat, and cholesterol than the low fat diet group ($P < 0.01$ for all comparisons).

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Calorie-restricted, moderately low-fat diet with recommended macronutrient distribution of 55% carbohydrate, 15% protein and 30% fat.

Brehm 2003 (Continued)

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: 20 women with mean (SD) age 43.10 (8.56) years, mean (SD) weight 92.31 (6.0) kg's, mean (SD) BMI 34.04 (1.83) kg/m², mean (SD) systolic BP 115 (2.47) mmHg, mean (SD) diastolic BP 75 (1.99) mmHg, mean (SD) total cholesterol 184.45 (6.07) mg/dL, mean (SD) triglycerides 109.25 (9.49) mg/dL, mean (SD) LDL 113.80 (6.36) mg/dL, mean (SD) HDL 48.75 (2.23) mg/dL, mean (SD) glucose 91.1 (2.1) mg/dL

Why? NR

What (materials)? Self-testing kits for ketosis, cooking tips, food diaries and pedometers (worn for 3 days a week). No specific exercise routine

What (procedures)? Participants were instructed on a calorie-restricted, moderately low-fat diet with a recommended macronutrient distribution of 55% carbohydrate, 15% protein, and 30% fat. Calorie prescriptions were based on body size and calculated using the Harris-Benedict equation. Group meetings addressed cooking tips, stress management, behaviour modification, and relapse prevention. Subjects were advised to continue their baseline level of activity. At the end of the 3-month intervention, subjects were instructed to continue with their weight loss efforts, but without scheduled contact with the dietitians until the 6-month assessment. Registered dietitians delivered a 3-month intervention via biweekly group meetings (addressing cooking tips, stress management, behaviour modification, and relapse prevention) and alternating individual meetings with the assigned dietitian.

Who provided? Dietitians provided the intervention and the research nurses did the assessments.

How and where? Face-to-face group sessions, location University of Cincinnati campus

When and how much? Two registered dietitians delivered a 3-month intervention aimed at promoting dietary compliance. Group meetings with subjects on the same diet were held biweekly. On alternating weeks, subjects met for individual counselling session.

Strategies to improve or maintain fidelity; tailoring and modification: "On alternating weeks, subjects met for individual counseling session during which their assigned dietitian reviewed their 3-d food records from the previous week, analyzed by Nutritionist V (First Data Bank, San Bruno, CA), and provided dietary recommendations and positive reinforcement."

Extent of intervention fidelity: The low-fat diet group had daily calories distributed as 54% carbohydrate, 18% protein, and 28% fat.

Concomitant interventions: NR

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: No

Change in BMI (kg/m²) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: No

Change in SBP (mmHg) at ≥ 12 months: No

All-cause mortality at ≥ 12 months: No

Brehm 2003 (Continued)

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥ 12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: No

Change in LDL (mmol/L) at ≥ 12 months: No

Change in HDL (mmol/L) at ≥ 12 months: No

Change in non-HDL (mmol/L) at ≥ 12 months: No

Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: No

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: No

Participant-reported adverse effects: No

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Primary reference had blood pressure values (baseline), but for 20 participants only. Values not extracted

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Very low carbohydrate diet, dieters instructed to follow an ad libitum diet with a maximum intake of 20 g/d carbohydrate to induce ketosis. After 2 weeks subjects were permitted to increase their intake of carbohydrates to 40-60 g/d only if testing of urinary ketones continued to indicate ketosis.

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? No

Recipients: N = 42 females only, mean (SE) age 44.5 (1.4) years, mean (SE) weight 90.9 (1.4) kg, mean (SE) BMI 33.2 (0.4) kg/m².

Why? Low carbohydrate diets increase energy expenditure leading to weight loss.

What (materials)? Food records and pedometer

What (procedures)? Participants were instructed to follow an ad libitum diet with a maximum intake of 20 g of carbohydrate per day, with the intent of producing ketosis. After 2 wk of dieting, subjects were permitted to increase their intake of carbohydrate to 40-60 g/d only if self-testing of urinary ketones continued to indicate ketosis. Energy prescriptions were based on body size and calculated using the Harris-Benedict equation plus an activity factor. All subjects were advised to continue their baseline level of physical activity. Group meetings with subjects on the same diet were held biweekly and addressed cooking tips, stress management, behavior modification, and relapse prevention. On alternating weeks, subjects met for individual counselling sessions during which their assigned dietitian reviewed their 3-d food records and pedometer records from the previous week and provided dietary recommendations and positive reinforcement.

Who provided? "Two counseling dietitians were trained to provide instruction on both diets. Each dietitian counseled half of the LC group and half of the LF group. This was done in order to minimize bias resulting from any differences in instruction by the dietitians."

Brehm 2005 (Continued)

How and where? Face-to-face, individual and group sessions; General Clinical Research Center (GCRC) of Cincinnati Children's Hospital Medical Center

When and how much? Weekly counselling with a registered dietitian during the first half of the study with alternating group and individual sessions each week. Group sessions lasted 1h and individual counselling sessions were 30 min each. After the study's midpoint, the subjects followed their assigned diets on their own.

Strategies to improve or maintain fidelity; tailoring and modification: Subjects kept 3-day diet records in which they recorded their entire food and beverage intake for 3 consecutive days each week. The study dietitian assigned to each subject reviewed the diet records for completeness, and provided ongoing instruction to the subjects on how to accurately record dietary intake.

Extent of intervention fidelity: Though only the LF dieters were instructed to restrict energy intake, both groups significantly reduced their daily energy intake from baseline. As expected, intakes of dietary fat and protein by the LF group at the end of the intervention were significantly lower than baseline (though protein increased as a percent of total energy intake).

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Calorie-restricted, moderately low-fat diet with recommended macronutrient distribution of 55% carbohydrate, 15% protein and 30% fat.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 39 females only, mean (SE) age 41.9 (1.8) years, mean (SE) weight 91.3 (1.2) kg, mean (SE) BMI 33.8 (0.4) kg/m².

Why? NR

What (materials)? Food records and pedometer

What (procedures)? The other group of dieters was instructed to follow an energy-restricted, moderately low-fat diet with a recommended macronutrient distribution of 55% carbohydrate, 15% protein, and 30% fat. Energy prescriptions were based on body size and calculated using the Harris-Benedict equation plus an activity factor. All subjects were advised to continue their baseline level of physical activity. Group meetings with subjects on the same diet were held biweekly and addressed cooking tips, stress management, behaviour modification, and relapse prevention. On alternating weeks, subjects met for individual counselling sessions during which their assigned dietitian reviewed their 3-d food records and pedometer records from the previous week and provided dietary recommendations and positive reinforcement.

Who provided? "Two counseling dietitians were trained to provide instruction on both diets. Each dietitian counseled half of the LC group and half of the LF group. This was done in order to minimize bias resulting from any differences in instruction by the dietitians."

How and where? Face-to-face, individual and group sessions; General Clinical Research Center (GCRC) of Cincinnati Children's Hospital Medical Center

When and how much? Weekly counselling with a registered dietitian during the first half of the study with alternating group and individual sessions each week. Group sessions lasted 1h and individual counselling sessions were 30 min each. After the study's midpoint, the subjects followed their assigned diets on their own.

Strategies to improve or maintain fidelity; tailoring and modification: Subjects kept 3-day diet records in which they recorded their entire food and beverage intake for 3 consecutive days each week. The study dietitian assigned to each subject reviewed the diet records for completeness, and provided ongoing instruction to the subjects on how to accurately record dietary intake.

Brehm 2005 (Continued)

Extent of intervention fidelity: Not surprisingly, the LC diet group consumed significantly less carbohydrate by the end of the intervention, as compared to their baseline intake.

Concomitant interventions: NR

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

 Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Diet A: 40% carbohydrate, 30% protein and 30% fat. The daily caloric intake for weight loss was calculated as the total caloric requirement minus 1000 kcal.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Calleja-Fernández 2012 (Continued)

Exercise component? No

Recipients: 40% carb - participants were a mix of insulin sensitive and insulin resistant. Mean age 40.19 years, and mean BMI 31.87 kg/m²

Why? To evaluate the long-term effects on weight loss and insulin resistance of the diet in obese people either with insulin resistance (IR) or without insulin resistance (IS)

What (materials)? Written materials and daily food diary

What (procedures)? Daily energy requirements were estimated using the resting metabolic rate calculated by the Harris-Benedict equation, 10 and an activity factor of 1.5 was added in order to estimate the total caloric requirement. The daily caloric intake for weight loss was calculated as the total caloric requirement minus 1000 kcal. The subjects were free living and were asked to maintain their usual patterns of activity. Participants were prescribed a 40% carbohydrate, 30% protein and 30% fat diet. The dietitian was responsible for providing individual counselling and written material to the participants on the initial visit and then the patients were instructed to record their food intake in a daily food diary and to discuss it with the dietitian on each visit. Nutritional intake history, 24-hr dietary recall and written food records were also assessed at all visits.

Who provided? Dietitian

How and where? face-to-face, location NR

When and how much? "...visit every 2 weeks for 16 weeks at the beginning of the trial and on each 3 monthly visit for 1 year."

Strategies to improve or maintain fidelity; tailoring and modification: A 72-h dietary recall was performed at every visit. Same dietitian and personnel making assessments

Extent of intervention fidelity: NR

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Diet B: 55% carbohydrate, 15% protein and 30% fat. The daily caloric intake for weight loss was calculated as the total caloric requirement minus 1000 kcal.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: 55% carb - participants were a mix of insulin sensitive and insulin resistant. Mean age 41.58 years, and mean BMI 31.81 kg/m²

Why? To evaluate the long-term effects on weight loss and insulin resistance of the diet in obese people either with insulin resistance (IR) or without insulin resistance (IS)

What (materials)? Written materials and daily food diary

What (procedures)? Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate high-fat (LC/HF) diet, comprising 40% carbohydrate, 40% fat and 20% protein. Energy deficit of 400 kcal/day

Cornier 2005 (Continued)

Treatment diet type (carbohydrate-fat-protein): Low-high-balanced

Exercise component? No

Recipients: N = 11 women with a mean (SD) age of 42.35 (8.53), mean (SD) weight 87.79 (11.28) kg, mean (SD) BMI 32.69 (1.72) kg/m², mean (SD) total cholesterol 190.36 (37.62) mg/dL, mean (SD) HDL 44.73 (10.66) mg/dL, mean (SD) LDL 115 (30.04) mg/dL, mean (SD) triglycerides 150.64 (67.59) mg/dL who were either insulin sensitive or insulin resistant as per fasting insulin levels

Why? "We hypothesized that if in the insulin-sensitive (IS) individuals, insulin promotes better use of dietary CHOs, perhaps through increased dietary induced and/or cellular thermogenesis compared with the IR individuals, we might observe a greater weight loss in the IS group on a high-CHO (HC) hypocaloric diet."

What (materials)? All food was prepared and provided by the hospital kitchen. Participants picked up their diet every 3 days but ate the majority of the food at home.

What (procedures)? Participants were prescribed a hypocaloric diet (400 kcal deficit/d) comprised of 40% CHO, 40% fat, and 20% protein for 16 weeks. The polyunsaturated to monounsaturated to saturated fatty acid ratio (1:1:1) and fiber and cholesterol content of the diets were identical in both diets. The subjects were otherwise free-living and were expected not to consume food outside of the diet but could have eaten food in addition to or other than the diet. Subjects were asked to maintain their usual activity pattern and were regularly questioned regarding activity. Estimates of daily energy intake were made using 3-day food diary, 3-day control diet, and baseline RMR plus an activity factor.

Who provided? Dietitian

How and where? Face-to-face at the General Clinical Research Center (GCRC) at the University of Colorado Hospital

When and how much? Daily food was provided which was made in the kitchen and collected by participants for 16 weeks. Subjects were asked to maintain their usual activity pattern and were regularly questioned regarding activity. Once a week, subjects were weighed and met with a dietitian to determine compliance.

Strategies to improve or maintain fidelity; tailoring and modification: Weekly assessments by dietitian, food prepared by the trial kitchen

Extent of intervention fidelity: NR

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: High-carbohydrate low-fat (HC/LF) diet, comprising 60% carbohydrate, 20% fat and 20% protein. Energy deficit of 400 kcal/day

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 10 women with a mean (SD) age of 40.82 (9.08), mean (SD) weight 84.72 (5.74) kg, mean (SD) BMI 31.68 (2.29) kg/m², mean (SD) total cholesterol 186.8(54.31) mg/dL, mean (SD) HDL 48.2 (15.81) mg/dL, mean (SD) LDL 113.6 (30.99) mg/dL, mean (SD) triglycerides 131.2 (78.89) mg/dL who were either insulin sensitive or insulin resistant as per fasting insulin levels

Why? "...IR individuals might display a lesser response to an HC diet and respond better to an LC hypocaloric diet."

What (materials)? All food was prepared and provided by the hospital kitchen. Participants picked up their diet every 3 days but ate the majority of the food at home.

What (procedures)? Participants received a hypocaloric diet (400 kcal deficit/d) comprised of 60% CHO, 20% fat, and 20% protein for 16 weeks. The polyunsaturated to monounsaturated to saturated fatty acid ratio (1:1:1) and fiber and cholesterol content of the diets were identical in both diets. The

Cornier 2005 (Continued)

subjects were otherwise free-living and were expected not to consume food outside of the diet but could have eaten food in addition to or other than the diet. Subjects were asked to maintain their usual activity pattern and were regularly questioned regarding activity. Estimates of daily energy intake were made using 3-day food diary, 3-day control diet, and baseline RMR plus an activity factor.

Who provided? Dietitian

How and where? Face-to-face at the General Clinical Research Center (GCRC) at the University of Colorado Hospital

When and how much? Daily food was provided which was made in the kitchen and collected by participants for 16 weeks. Subjects were asked to maintain their usual activity pattern and were regularly questioned regarding activity. Once a week, subjects were weighed and met with a dietitian to determine compliance.

Strategies to improve or maintain fidelity; tailoring and modification: Weekly assessments by dietitian, food prepared by the trial kitchen

Extent of intervention fidelity: NR

Concomitant interventions: NR

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

Participants

Country and setting: UK, outpatient diabetes, endocrinology and metabolism research unit in Oxford

Eligibility criteria: Participants over 18 years of age with BMI > 25 kg/m² who do not have type 2 diabetes, or have type 2 diabetes treated by diet or metformin monotherapy. Participants were excluded if they had type 1 or type 2 diabetes treated with insulin, sulphonylurea or thiazolidinedione; were pregnant, of childbearing age without contraception or were breastfeeding; had major psychiatric disease including eating disorders; had a history of alcohol or drug abuse, abnormal liver function, known malignancy or serum creatinine level above 150 µmol/L.

Type 2 diabetes at baseline: Mixed; included persons with or without T2DM; at baseline 13/26 included did not have T2DM and 13/26 had T2DM; eligible outcome data was reported separately for participants with and without T2DM and was included in the appropriate comparisons where possible.

Impaired glucose tolerance at baseline: No

Dyson 2007 (Continued)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Triglycerides are geometric means. Discrepancy in reported percentage of male participants for the total group (25% in Dyson et al 2010, but 23% in Dyson et al 2007, the latter did not appear correct when looking at percentage per trial arm).

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low carbohydrate diet: carbohydrates 40 g/day, with a deficit of 500 kcal/d and physical activity for 30 min at least 5 days per week.

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? Yes

Recipients: Subjects were 17% male, aged mean (SD) 55 (5), with BMI mean (SD) 35.1 (6.8) and weight 95.6 (16.7) kgs

Why? Low-carbohydrate diets are effective for weight reduction in people without diabetes, but there is limited evidence for people with Type 2 diabetes.

What (materials)? Recipe booklet

What (procedures)? Low-carbohydrate diet (40 g/day). All subjects were encouraged to increase physical activity and advised to exercise at moderate intensity for 30 min at least 5 and preferably 7 days per week.

Who provided? Dietitian

How and where? NR

When and how much? 3 months of dietary intervention

Strategies to improve or maintain fidelity; tailoring and modification: NR

Extent of intervention fidelity: Significant reduction in energy intake in both groups, and a greater reduction in calories in the low-carbohydrate group (949 vs. 515 kcal/day, $P = 0.036$). There were no differences in changes in absolute protein and fat intakes between the two groups, but there was a highly significant reduction in carbohydrate intake in the low-carbohydrate group to 56.8 g/day. This reduction in carbohydrate intake was reflected in significant changes in %energy from macronutrients.

Concomitant interventions: Hypoglycemics

Control diet:

Name (as reported) and brief description: Low-fat diet following the nutritional recommendations of Diabetes UK, with a deficit of 500 kcal/d and physical activity for 30 min at least 5 days per week

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: Subjects were 36% male, aged mean (SD) 50 (12), with BMI mean (SD) 35.0 (7.4) and weight 97.0 (17.2) kgs

Why? NR

What (materials)? NR

Dyson 2007 (Continued)

What (procedures)? Low-fat diet (healthy eating advice). All subjects were encouraged to increase physical activity and advised to exercise at moderate intensity for 30 min at least 5 and preferably 7 days per week.

Who provided? Dietitian

How and where? NR

When and how much? 3 month of dietary intervention

Strategies to improve or maintain fidelity; tailoring and modification: NR

Ebbeling 2007 (Continued)

Other notes about participants: Triglyceride concentrations were skewed and assessed with Mann-Whitney-Wilcoxon test.

Interventions

Energy (E) comparison of treatment vs control diets: Unrestricted/ad libitum prescription in both diets

Treatment diet:

Name (as reported) and brief description: Low-glycemic load diet. The target macronutrient composition was 40% of energy from carbohydrate, emphasizing low-glycemic index sources, 35% from fat, and 25% from protein. Physical activity recommendations based on public health guidelines. Diet was prescribed using an ad libitum approach.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: N = 7 (19%) male, N = 29 (81%) female with overall mean (SD) age 28.2 (3.8) years, mean (SD) weight 103.5 (17.3) kg, mean (SD) LDL 102 (35) mg/dL, mean (SD) HDL 57 (20) mg/dL, mean (SD) triglycerides 112 (96) mg/dL, mean (SD) systolic BP 105 (12) mmHg and mean (SD) diastolic BP 63 (8) mmHg

Why? "Diets with a high glycemic load (the mathematical product of the glycemic index and the carbohydrate amount) result in higher postprandial insulin concentration, calorie for calorie, than those with a low glycemic load." Individuals with a high insulin response to glucose may be most sensitive to the effects of glycemic load. The purpose of this study was to determine whether insulin secretion affects body fat loss among obese individuals consuming self-prepared diets.

What (materials)? "Participants were equipped with food-choice lists that delineated products into low-, moderate-, and high-glycemic load categories. Registered dietitians provided information during cooking demonstrations to encourage consumption of low-glycemic load foods and led interactive activities using food models to define appropriate serving sizes of high-glycemic load foods (e.g. refined grain products, sweets)."

What (procedures)? Participants were counselled to consume low-glycemic load foods (particularly nonstarchy vegetables, legumes, and temperate fruits) and to limit intake of high-glycemic load foods (such as refined grains, starchy vegetables, fruit juices, and sweets). Attention also was directed toward consuming sources of healthful fat including nuts, seeds, and oils. The target macronutrient composition was 40% of energy from carbohydrate, emphasising low-glycemic index sources, 35% from fat, and 25% from protein. Nutrition education and dietary counselling were provided to participants. Registered dietitians provided information during cooking demonstrations to encourage consumption of low-glycemic load foods and led interactive activities using food models to define appropriate serving sizes. 23 group workshops and 1 private counselling session each one for an hour as well as 5 motivational telephone calls for 30 mins each were conducted. Six of the group workshops were scheduled during the first 2 months of the intervention period, and the remaining workshops were held on a monthly basis thereafter. The private session occurred during the initial month, and a telephone call was scheduled for each of the subsequent 5 months of the intensive intervention period. Participants were asked to keep one 3-day food diary prior to each workshop, particularly during the intensive intervention period. Three unannounced telephone-administered 24-hour recall interviews were conducted at baseline and again at 6, 12, and 18 months to assess diet and physical activity.

Who provided? Registered dietitian

How and where? Face-to-face group sessions as well as private sessions, location NR

When and how much? "There were 23 group workshops (1 hour each), 1 private counseling session (1 hour), and 5 motivational telephone calls (30 minutes each). Six of the group workshops were scheduled during the first 2 months of the intervention period, and the remaining workshops were held on a monthly basis thereafter. The private session occurred during the initial month, and a telephone call was scheduled for each of the subsequent 5 months of the intensive intervention period."

Strategies to improve or maintain fidelity; tailoring and modification: "Principles of nonformal adult education and participant centered counseling were applied to promote adherence to the di-

Ebbeling 2007 (Continued)

ets. Respectful consideration of participant perspectives, core values, life experiences, current circumstances, and available resources formed a foundation for education and counseling. Participants were asked to keep a food diary (prior to each workshop). Dietitians prepared written feedback on submitted diaries, highlighting successes and providing advice for correcting deviations from diet prescriptions. Several strategies were used to maximize treatment fidelity. First, group workshops were scripted and written educational materials were developed to ensure delivery of well-defined nutrition messages for each diet group; otherwise, the format of the workshops and quality of the materials were completely parallel to maintain equal treatment intensity. Second, flowcharts provided structure for the private session and motivational telephone calls and were used to foster dietitian adherence to a participant centered counseling model, with adequate flexibility for addressing situations unique to each individual. Prompts for open-ended questions were included in the flowcharts to enhance dialogue. The private session and telephone calls were digitally recorded, such that the study director and lead dietitian could monitor deviations from the protocol and provide feedback to dietitians as necessary. The duration of the private session and each telephone call also was monitored as an indicator of integrity with regard to treatment intensity. Third, weekly staff meetings provided an opportunity for continued discussion on intervention delivery, particularly strategies for assisting individual participants without compromising differentiation between diets. Fourth, dietitians were given detailed guidelines for providing written feedback on food diaries to avoid unintended overlap in dietary advice between groups. Participant adherence was evaluated based on attendance at group workshops and private sessions, completion of motivational telephone called and self-reported dietary intake. In addition, data were obtained in regard to physical activity and participant satisfaction with program."

Extent of intervention fidelity: For the low-glycemic load group, glycemic index and carbohydrate intake decreased, producing a significant mean (SE) decrease in glycemic load (-19.8 [2.5] g/1000 kcal; $P = 0.001$). Total dietary fat increased (mean [SE], 3.0% [1.3%] of energy; $P = 0.02$) whereas saturated fat did not change (mean [SE], 0.5% [0.6%] of energy; $P = 0.36$). Treatment intensity did not differ between diet groups ($P > 0.40$). On average, participants attended a mean (SE) of 13.4 (0.7) of the 23 scheduled workshops and completed 5.4 (0.2) of the 6 planned individual contacts with a registered dietitian. They provided food diaries on a mean (SE) of 5.6 (0.3) occasions during the 6-month intensive intervention period. Satisfaction with the programme also did not differ between groups.

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Low-fat diet. The target macronutrient composition was 55% of energy from carbohydrate, 20% from fat, and 25% from protein. Physical activity recommendations based on public health guidelines. Diet was prescribed using an ad libitum approach

Control diet type (carbohydrate-fat-protein): Balanced-balanced-high

Exercise component? Yes

Recipients: N = 8 (22%) male, N = 29 (78%) female with overall mean (SD) age 26.9 (4.2) years, mean (SD) weight 103.3 (15.1) kg, mean (SD) LDL 126 (34) mg/dL, mean (SD) HDL 54 (13) mg/dL, mean (SD) triglycerides 126 (81) mg/dL, mean (SD) systolic BP 108 (11) mmHg and mean (SD) diastolic BP 62 (9) mmHg

Why? NR

What (materials)? "Participants were equipped with food-choice lists that delineated products into low-, moderate-, and high-glycemic load categories.  Participants

Country and setting: Israel, urban outpatient primary care clinics in the central district

Eligibility criteria: Participants aged 30 to 65 years with BMI 27 to 34 kg/m², diagnosis of type 2 diabetes within the past one to 10 years, last values of 7 to 10% for HbA1c, 1.8 to 4.5 mmol/L for plasma triglycerides, < 123.2 µmol/L for serum creatinine and no change in diabetes medication in the three months prior. Participants were excluded if they had proliferative diabetic retinopathy, active cancer or psychiatric disease, current insulin treatment or uncontrolled hypo- or hyperthyroidism.

Type 2 diabetes at baseline: Yes

Impaired glucose tolerance at baseline: No

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Mixed

Total number randomised: 259

Total attrition in trial: 80

Treatment diet

Participants randomised: 85

Participants withdrawn (voluntary): 6

Total attrition: 24

Control diet:

Participants randomised: 89

Participants withdrawn (voluntary): 1

Total attrition: 26

Baseline data treatment diet:

Randomised participants not included: 24/85

Age (years): mean (SD) 55.5 (6.5)

Gender distribution (as reported): female 30/61 (49.2%), male 31/61 (50.8%)

Weight (kg): mean (SD) 86.7 (14.3)

BMI (kg/m²): mean (SD) 31.4 (2.8)

HDL (mmol/L): mean (SD) 1.1 (0.2)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.5 (0.8)

TG (mmol/L): mean (SD) 3.0 (0.7)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate Mediterranean (LCM); 35% carbohydrates (30 g fibre), 45% fat (23% MUFA, 15% PUFA and 7% SFA) and 20% protein. Physical activity three times a week for 30 to 45 min. Calories prescribed as 20/kg body weight

Treatment diet type (carbohydrate-fat-protein): Low-high-balanced

Exercise component? Yes

Recipients: 30 (49.2%) females and 31 (50.8%) males with mean (SD) age of 55.5 (6.5) years, mean (SD) years since DM diagnosis 5.5 (3.8), mean (SD) weight 86.7 (14.3) kg, mean (SD) BMI 31.4 (2.8) kg/m², mean (SD) HbA1c 8.3 (1.0) %, mean (SD) fasting plasma glucose 10.5 (2.0) mmol/L, mean (SD) total cholesterol 5.4 (0.9) mmol/L, mean (SD) HDL 1.1 (0.2) mmol/L, mean (SD) LDL 3.1 (0.8) mmol/L, mean (SD) triglycerides 3.2 (0.8) mmol/L

Why? The relative importance of glycaemic index and of glycaemic load as well as the relative advantages of higher fat diets and the type of dietary fat vs. diets with high carbohydrate content are unclear.

What (materials)? NR

What (procedures)? All dietitians followed a structured protocol for the scheduled meetings. The LCM diet included only LGI carbohydrates. The diet provided 35% carbohydrate and 45% fat from total ener-

Elhayany 2010 (Continued)

gy. Participants were counselled to eat 4–6 meals/day according to their lifestyle. All patients were advised to engage in 30–45 min of aerobic activity at least 3 days a week.

Who provided? Dietitians. All the dietitians participated in a training workshop to ensure standardisation in questionnaire administration.

How and where? Face-to-face meetings in community setting

When and how much? Every two weeks for one year (24 meetings)

Strategies to improve or maintain fidelity; tailoring and modification: Participants completed a 24-h food recall questionnaire, a validated food frequency questionnaire (FFQ) and a physical activity questionnaire that included quality of life measures, at baseline, 3 and 6 months. Dietary adherence only assessed from the dietary data collected at 6 months

Extent of intervention fidelity: 13 participants excluded during follow-up due to non-compliance. The mean reported energy intake was similar in the three diets (2221.6 calories \pm 1086.6).

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Traditional Mediterranean (TM); 50% carbohydrates (30 g fibre), 30% fat (10% MUFA, 12% PUFA and 7% SFA) and 20% protein. Physical activity three times a week for 30 to 45 min. Calories prescribed as 20/kg body weight

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: 28 (44.4%) females and 35 (55.6%) males with mean (SD) age 57.4 (6.1) years, mean (SD) years since DM diagnosis 6.2 (9.9), mean (SD) weight 85.5 (10.6) kg, mean (SD) BMI 31.1 (2.8) kg/m², mean (SD) HbA1c 8.3 (1.0) %, mean (SD) fasting plasma glucose 10.1 (1.8) mmol/L, mean (SD) total cholesterol 5.5 (0.8) mmol/L, mean (SD) HDL 1.1 (0.2) mmol/L, mean (SD) LDL 3.2 (0.8) mmol/L, mean (SD) triglycerides 3.0 (0.7) mmol/L

Why? The relative importance of glycaemic index and of glycaemic load as well as the relative advantages of higher fat diets and the type of dietary fat vs. diets with high carbohydrate content are unclear.

What (materials)? NR

What (procedures)? All dietitians followed a structured protocol for the scheduled meetings. The TM diet included only LGI carbohydrates. Prescribed TM diet with carbohydrates (50–55%), fat (30%) and protein (15–20%) where carbohydrate sources come from low-glycemic index foods. Participants were counselled to eat 4–6 meals/day according to their lifestyle. All patients were advised to engage in 30–45 min of aerobic activity at least 3 days a week.

Who provided? Dietitians. All the dietitians participated in a training workshop to ensure standardisation in questionnaire administration.

How and where? Face-to-face meetings in community setting

When and how much? Every two weeks for one year (24 meetings)

Strategies to improve or maintain fidelity; tailoring and modification: Participants completed a 24-h food recall questionnaire, a validated food frequency questionnaire (FFQ) and a physical activity questionnaire that included quality of life measures, at baseline, 3 and 6 months. Dietary adherence only assessed from the dietary data collected at 6 months

Extent of intervention fidelity: 11 participants excluded during follow-up due to non-compliance. The mean reported energy intake was similar in the three diets (2221.6 calories \pm 1086.6).

Concomitant interventions: NR

Outcomes

Change in body weight (kg) at 3 to < 12 months: No

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

104

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description:

High-protein diet prescribing 30% protein (~110 g/day), 40% carbohydrates (150 g/day) and 30% fat (~50 g/day). Energy intake decreased by 500 and 800 kcal from daily energy requirements

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: N = 7 women and N = 26 men with mean (SD) age 57.3 (10.1) years, mean (SD) weight 105.5 (22.4) kg, mean (SD) BMI 36.2 (7.1) kg/m², mean (SD) total cholesterol 160.2 (41.9) mg/dL, mean (SD) LDL-cholesterol 85.5 (32.2) mg/dL, mean (SD) HDL-cholesterol 37.9 (10.6) mg/dL, mean (SD) triglyc-

Evangelista 2021 (Continued)

erides 163.2 (59.2) mg/dL, mean (SD) diastolic blood pressure 72.8 (9.6) mmHg, mean (SD) systolic blood pressure 123.3 (12.8) mmHg, N = 33 (100%) had heart failure and diabetes mellitus/impaired fasting glucose, N = 15 (46%) had hypertension, N = 9 (27%) had coronary artery disease, and N = 12 (36%) were previous smokers.

Why? Examining the role of a high-protein diet consumed over 12 weeks in slowing the progression heart failure and diabetes mellitus

What (materials)? Participants were prescribed a hypocaloric diet incorporating a 500 to 800 kcal deficit per day into their individualised energy requirements. This was done through the provision of a standard structured energy-restricted meal plan. Participants were provided with a 'Participant Handbook' containing resources (such as lists of food items and serving sizes) and tools (such as weight charts, food checklists and three-day food records). Participants were also provided with a pedometer.

What (procedures)? The high-protein diet consisted of 12 weeks following a diet with a macronutrient composition of 30% fat (~50 g/day), 40% carbohydrate (150 g/day) and 30% protein (~110 g/day). Participants were also encouraged to exercise regularly to promote weight loss, by engaging in 20 to 30 minutes of physical activity. Diet counselling sessions were provided.

Who provided? A licenced dietitian provided the counselling sessions.

How and where? Face-to-face counselling sessions were provided; the location of sessions was not reported. Sessions were on a one-to-one basis. Spouses, significant family members or friends were asked to participate in the sessions, if appropriate.

When and how much? Counselling sessions were provided at visits at baseline, 2, 4, 8 and 12 weeks. The duration of sessions was between 45 to 60 minutes. The dietitian provided detailed information on the meal plan and keeping daily food logs.

Strategies to improve or maintain fidelity; tailoring and modification: Participants received a list of counselling appointments at baseline, and were reminded of sessions by phone call, text or email before each visit. The body weight, waist circumference and dietary intake of participants were reviewed at each visit; dietary adjustments were made if necessary. The dietitian reviewed completed dietary checklists and three-day food records. The latter was done to clarify captured information, verify portions and obtain data that were incomplete. Pedometers were used by participants to monitor their own physical activity, changes in activity were also captured at each follow-up visit. The authors also reported the following strategies to improve adherence: establishing a trusting relationship with participants; expressing appreciation for participation with cards and phone calls; providing easy access to investigators and research staff; providing culturally sensitive meal plans; paying for parking during visits; recognising potential barriers and helping to identify solutions; and enlisting family support. Early recognition of non-adherence, identified through three-day food records, prompted additional education of participants and removal of obstacles.

Extent of intervention fidelity: Three-day food records reviewed at each visit were used to assess adherence. The authors reported "high adherence" as a strength of the study.

Concomitant interventions: Of intervention participants; 82% were treated with ACE inhibitors, 21% with angiotensin receptor blockers, 88% with beta-blockers, 70% with diuretics, 36% with digoxin, 33% with pain medication and 18% with antidepressants.

Control diet:

Name (as reported) and brief description: Standard-protein diet prescribing 15% protein (~55 g/day), 55% carbohydrates (~200 g/day) and 30% fat (~50 g/day). Energy intake decreased by 500 and 800 kcal from daily energy requirements

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: N = 14 women and N = 29 men with mean (SD) age 58.0 (9.6) years, mean (SD) weight 109.9 (19.3) kg, mean (SD) BMI 37.3 (5.4) kg/m², mean (SD) total cholesterol 163.7 (39.9) mg/dL, mean (SD) LDL-cholesterol 94.0 (32.4) mg/dL, mean (SD) HDL-cholesterol 40.0 (9.2) mg/dL, mean (SD) triglycerides 154.0 (65.1) mg/dL, mean (SD) diastolic blood pressure 73.30 (1.0) mmHg, mean (SD) systolic blood

Evangelista 2021 (Continued)

pressure 116.8 (19.5) mmHg, N = 43 (100%) had heart failure and diabetes mellitus/impaired fasting glucose, N = 20 (47%) had hypertension, N = 13 (30%) had coronary artery disease, and N = 19 (44%) were previous smokers.

Why? Examining the role of a standard-protein diet consumed over 12 weeks in the progression of heart failure and diabetes mellitus, compared to a diet higher in protein

What (materials)? Participants were prescribed a hypocaloric diet incorporating a 500 to 800 kcal deficit per day into their individualised energy requirements. This was done through the provision of a standard structured energy-restricted meal plan. Participants were provided with a 'Participant Handbook' containing resources (such as lists of food items and serving sizes) and tools (such as weight charts, food checklists and three-day food records). Participants were also provided with a pedometer.

What (procedures)? The standard-protein diet consisted of 12 weeks following a diet with a macronutrient composition of 30% fat (~50 g/day), 55% carbohydrate (~200 g/day) and 15% protein (~55 g/day). Participants were also encouraged to exercise regularly to promote weight loss, by engaging in 20 to 30 minutes of physical activity. Personalised nutritional counselling sessions were provided.

Who provided? A licenced dietitian provided the counselling sessions.

How and where? Face-to-face counselling sessions were provided; the location of sessions was not reported. Sessions were on a one-to-one basis. Spouses, significant family members or friends were asked to participate in the sessions, if appropriate.

When and how much? Counselling sessions were provided at visits at baseline, 2, 4, 8 and 12 weeks. The duration of sessions was between 45 to 60 minutes. The dietitian provided detailed information on the meal plan and keeping daily food logs.

Strategies to improve or maintain fidelity; tailoring and modification: Participants received a list of counselling appointments at baseline, and were reminded of sessions by phone call, text or email before each visit. The body weight, waist circumference and dietary intake of participants were reviewed at each visit; dietary adjustments were made if necessary. The dietitian reviewed completed dietary checklists and three-day food records. The latter was done to clarify captured information, verify portions and obtain data that were incomplete. Pedometers were used by participants to monitor their own physical activity, changes in activity were also captured at each follow-up visit. The authors also reported the following strategies to improve adherence: establishing a trusting relationship with participants; expressing appreciation for participation with cards and phone calls; providing easy access to investigators and research staff; providing culturally sensitive meal plans; paying for parking during visits; recognising potential barriers and helping to identify solutions; and enlisting family support. Early recognition of non-adherence, identified through three-day food records, prompted additional education of participants and removal of obstacles.

Extent of intervention fidelity: Three-day food records reviewed at each visit were used to assess adherence. The authors reported "high adherence" as a strength of the study.

Concomitant interventions: Of control participants; 63% were treated with ACE inhibitors, 37% with angiotensin receptor blockers, 95% with beta-blockers, 72% with diuretics, 42% with digoxin, 26% with pain medication and 19% with antidepressants.

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Other notes about participants: Number of participants not included in baseline characteristics for total cholesterol, LDL, HDL and triglycerides: intervention 5/33; control 5/33

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High protein diet: 30% of energy as protein, 40% as carbohydrate, and 30% as fat 8% of energy as saturated, 12% as monounsaturated, and 5% as polyunsaturated fatty acids. Energy restriction of 6400 kJ per day on average

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: N = 7 men and N = 21 women, mean (SD) age 50.93 (11.43) years, mean (SD) weight 93.98 (13.54) kg, mean (SD) BMI 34.3 (3.82) kg/m², with fasting insulin levels greater than 12 mU/L (mean 16 mU/L).

Why? "There are no data on the effects of high-protein diets on changes in bone resorption and blood pressure after moderate weight loss. HP diet would spare lean mass and result in greater decreases in fasting and postprandial insulin concentrations."

What (materials)? The diets were prescriptive fixed-menu plans, and subjects were supplied with key foods that made up 60% of their energy intake. The key foods supplied to both diet groups were preweighed meat and poultry, shortbread biscuits, canola margarine (Canola Lite; Meadow Lea Foods Ltd, Mascot, Australia), and high-oleic acid sunflower oil (Sunola; Meadow Lea Foods Ltd). The HP diet group also received low-fat (3% fat) cheese (Kraft Free; Kraft Foods Ltd, Melbourne, Australia) and skim milk powder.

What (procedures)? Participants were prescribed a HP diet: 30% of energy as protein (= 110 g/d), 40% as carbohydrate, and 30% as fat for 16 weeks. The fatty acid profiles for each diet were matched (8% of energy as saturated, 12% as monounsaturated, and 5% as polyunsaturated fatty acids). Each subject completed weighed daily checklists of all foods consumed. Group training in the use of scales and

Farnsworth 2003 (Continued)

in keeping food records was provided. Both dietary groups underwent 12 wks of energy restriction (roughly 30% restriction of total energy, or 6.4 MJ on average), followed by 4 wks of energy balance with the same macronutrient composition. Participants also recorded physical activity.

Who provided? Dietitian

How and where? The study was conducted on an outpatient basis, location NR.

When and how much? 2-wk intervals over 16 weeks according to the method described by Parker et al (25)

Strategies to improve or maintain fidelity; tailoring and modification: Each subject completed weighed daily checklists of all foods consumed and was assessed by the same dietitian at 2-wk intervals according to the method described by Parker et al

Extent of intervention fidelity: As prescribed protein was higher and the carbohydrate was lower with the HP diet.

Concomitant interventions: Anti-hypertensive or lipid lowering medication and supplements

Control diet:

Name (as reported) and brief description: Standard protein diet: 15% of energy as protein, 55% as carbohydrate, and 30% as fat with 8% of energy as saturated, 12% as monounsaturated, and 5% as polyunsaturated fatty acids. Energy restriction of 6400 kJ per day on average

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 7 men and N = 22 women, mean (SD) age 50.12 (9.43) years, mean (SD) weight 93.39 (14.31) kg, mean (SD) BMI 33.82 (3.75) kg/m², with fasting insulin levels greater than 12 mU/L (mean 16 mU/L)

Why? NR

What (materials)? The diets were prescriptive fixed-menu plans, and subjects were supplied with key foods that made up 60% of their energy intake. The key foods supplied to both diet groups were preweighed meat and poultry, shortbread biscuits, canola margarine (Canola Lite; Meadow Lea Foods Ltd, Mascot, Australia), and high-oleic acid sunflower oil (Sunola; Meadow Lea Foods Ltd). The SP diet group received rice and rice noodles.

What (procedures)? Participants were prescribed a SP diet: 15% of energy as protein (roughly 60 g/d), 55% as carbohydrate, and 30% as fat. The fatty acid profiles for each diet were matched (8% of energy as saturated, 12% as monounsaturated, and 5% as polyunsaturated fatty acids). Both dietary groups underwent 12 wks of energy restriction (roughly 30% restriction of total energy, or 6.4 MJ on average), followed by 4 wks of energy balance with the same macronutrient composition. A weighed daily checklist of all foods consumed was required and a dietitian assessed the diet individually every 2 weeks. Also, group training in the use of scales and in keeping food records was provided.

Who provided? Dietitian

How and where? The study was conducted on an outpatient basis, location NR.

When and how much? 2-wk intervals over 16 weeks according to the method described by Parker et al (25)

Strategies to improve or maintain fidelity; tailoring and modification: Each subject completed weighed daily checklists of all foods consumed and was assessed by the same dietitian at 2-wk intervals according to the method described by Parker et al

Extent of intervention fidelity: NR

Concomitant interventions: Anti-hypertensive or lipid lowering medication and supplements

Total number of trial arms: 2

Year trial started: 2005

Sample size calculation: Yes

Outcome(s) used for sample size calculation: Difference in weight loss

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 52 weeks

What was the duration of the weight maintenance phase: NA

Other notes about methods: NA

Participants

Country and setting: USA, outpatient general clinical research centre in Columbus

Eligibility criteria: Participants were overweight and obese premenopausal women aged 30 and above with BMI of 25 to 34 kg/m²; with no prior diagnosis of cancer (except nonmelanoma skin cancer) and medical clearance from their primary physician. Participants were excluded if they were pregnant or planning to become pregnant; were currently participating in a weight loss program; had medical conditions which preclude adherence or had uncontrolled existing medical conditions.

Type 2 diabetes at baseline: Unclear; stratified with non-T2DM since fasting insulin levels provided by author were mostly not indicative of diabetes.

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Female

Total number randomised: 79

Total attrition in trial: 33

Treatment diet

Participants randomised: 38

Participants withdrawn (voluntary): NR

TC (mmol/L): mean (SD) 5.12 (0.93)

TG (mmol/L): NR

Group differences at baseline: NR

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: DBP and SBP baseline data not available for all randomised participants: intervention 2/38; control 1/41

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate diet comprising 40% carbohydrates, 30% protein and 30% fat with exercise (10,000 steps a day). Each participant provided with a calorie goal based on the Harris-Benedict equation

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: Subjects were 100% female, aged mean (SD) 41.9 (5.4) years, BMI (SD) 30.1 (2.6).

Why? We evaluated the effects of low-fat and low-carbohydrate weight-loss diets on longitudinal measures of blood pressure and blood lipids among overweight or obese premenopausal women who were also advised to increase their level of physical activity. We hypothesised that we would observe

Foraker 2014 (Continued)

favourable changes over time in blood pressure and blood lipids in both diet groups but that results would differ by level of adherence to the respective diet protocol and baseline presence of hypertension or hyperlipidemia.

What (materials)? Digiwalker pedometer to count daily steps

What (procedures)? LCD: 40% of total calories from carbohydrates, 30% from protein and 30% from fat plus physical activity. All participants were educated on caloric restriction and given personalised PA prescriptions. Each participant met with an RD at the university's Clinic Research Centre (CRC) once per week for the first month of the study period, every three weeks during the second, third and fourth months of the study, and every 6 weeks for the remainder of the study, except weeks 34 and 52, which were clinic visits. All women received counselling regarding their respective calorie-restricted diet, along with an individualised physical-activity prescription to promote weight loss. If a participant couldn't make it, telephonic counselling sessions were arranged. Each participant was advised to walk 10,000 steps per day.

Who provided? Dietitian

How and where? Face-to-face individually or telephonically at the Clinical Research Centre

When and how much? Weekly sessions for the first month, every 3 weeks for until month 4 then every 6 weeks

Strategies to improve or maintain fidelity; tailoring and modification: If a participant was unable to attend a meeting with the RD, sessions were conducted by telephone. Adherence to the dietary interventions was assessed through 7-day dietary recalls.

Extent of intervention fidelity: Adherence to the dietary interventions was low for both arms (22% and 29% for LFD and LCD, respectively). Overall, participants were more compliant with the PA component of the intervention (66% and 61% among those randomised to the LFD and LCD arms, respectively).

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Low-fat diet comprising 60% carbohydrates, 20% protein and 20% fat with exercise (10,000 steps a day). Each participant provided with a calorie goal based on the Harris-Benedict equation

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: Subjects were 100% female, aged mean (SD) 40.9 (5.1) years, BMI (SD) 30.5 (2.9)

Why? We evaluated the effects of low-fat and low-carbohydrate weight-loss diets on longitudinal measures of blood pressure and blood lipids among overweight or obese premenopausal women who were also advised to increase their level of physical activity. We hypothesised that we would observe favourable changes over time in blood pressure and blood lipids in both diet groups but that results would differ by level of adherence to the respective diet protocol and baseline presence of hypertension or hyperlipidemia.

What (materials)? Digiwalker pedometer to count daily steps.

What (procedures)? LFD: 20% of total calories from fat, 20% from protein and 60% from carbohydrates plus physical activity. All participants were educated on caloric restriction and given personalised PA prescriptions. Each participant met with an RD at the university's Clinic Research Centre (CRC) once per week for the first month of the study period, every three weeks during the second, third and fourth months of the study, and every 6 weeks for the remainder of the study, except weeks 34 and 52, which were clinic visits. Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.02 (0.83)

TG (mmol/L): mean (SD) 1.39 (0.93)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Carbohydrate prescription in intervention group was incremental; data only extracted up to 6 months.

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Foster 2003 (Continued)

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate, high-protein, high-fat (Atkins) ad libitum diet; carbohydrates limited to 20 g/d for the first two weeks and then gradually increased by 5 g/d per week until participants were within 2.2 to 4.5 kg from their goal weight [only low-carbohydrate for the first 6 months].

Treatment diet type (carbohydrate-fat-protein): Very low8w to low20w-unclear-unclear

Exercise component? No

Recipients: Participants were 63.6% female, aged 44.0 (9.4), with BMI 33.9 (3.8) and weight 98.7 (19.5) kg.

Why? Low-carbohydrate, high-protein and high-fat diets are increasingly popular, and are promoted by many best-selling books to promote weight loss and prevent risk factors for coronary heart disease in obese persons.

What (materials)? 'Dr. Atkins' New Diet Revolution' book (Atkins 1998).

What (procedures)? Participants were prescribed a limited carbohydrate diet with no restriction of fat and protein, with gradual increase of carbohydrate over time [only the first six months was eligible]. Participants receiving the LCD met individually with a registered dietitian before beginning the programme to review the central features of the diet.

Who provided? Dietitian

How and where? Individual face-to-face meetings, location NR

When and how much? The duration of [eligible] intervention comparison was six months. An initial meeting at baseline with the dietitian reviewed the central features of the diet; follow-up meetings with dietitians, to review dietary issues, were between 15 and 30 minutes long and occurred at three, six and 12 [ineligible] months.

Strategies to improve or maintain fidelity; tailoring and modification: Face-to-face meetings with dietitians to review dietary issues, weigh-ins at follow-up visits

Extent of intervention fidelity: Adherence was reported as poor, lack of statistical significance at 12 months was interpreted as a lack of adherence to the Atkins diet, but the comparison at 12 months was ineligible.

Concomitant interventions: Daily multi-vitamins

Control diet:

Name (as reported) and brief description: LEARN program for weight management, approximately 60% of calories from carbohydrates, 25% from fat and 15% from protein. Low-calorie, 1200 to 1500 kcal per day for women and 1500 to 1800 kcal per day for men

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Participants were 73.3% female, aged 44.2 (7.0), with BMI 34.4 (3.1) and weight 98.3 (16.4) kg.

Why? To assess whether a conventional diet is better in promoting weight loss and preventing risk factors for coronary heart disease in obese persons

What (materials)? A copy of The LEARN Program for Weight Management 17 which provided 16 lessons covering various aspects of weight control

What (procedures)? Participants were prescribed a high-carbohydrate, low-fat, low-calorie diet and were instructed how to count calories. A 15- to 30-minute session with a registered dietitian at 3, 6, and 12 months to review dietary issues. Participants receiving the HCD met individually with a registered di-

Foster 2003 (Continued)

etitian before beginning the programme to review the components of a HCD and to receive instructions about calorie counting.

Who provided? Dietitian

How and where? Individual face-to-face meetings, location NR

When and how much? The duration of [eligible] intervention comparison was six months. An initial meeting at baseline with the dietitian reviewed the components of the diet; follow-up meetings with dietitians, to review dietary issues, were between 15 and 30 minutes long and occurred at three, six and 12 [ineligible] months.

Strategies to improve or maintain fidelity; tailoring and modification: Face-to-face meetings with dietitians to review dietary issues, weigh-ins at follow-up visits

Extent of intervention fidelity: Adherence was reported as poor.

Concomitant interventions: Daily multi-vitamins

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate ad libitum diet, participants were instructed to limit carbohydrates to 20 g/d in the form of low GI vegetables. After 12 weeks participants gradually increased carbohydrate intake by 5 g/d/week by consuming more vegetables, limited amounts of fruits and eventually small quantities of whole grains and dairy products. Physical activity prescribed.

Treatment diet type (carbohydrate-fat-protein): Very low18w to low20w-unclear-unclear

Exercise component? Yes

Recipients: N = 50 (33%) males and N = 103 (67%) females with overall mean (SD) age 46.2 (9.2) years, mean (SD) BMI 36.1 (3.59) kg/m², mean (SD) weight 103.3 (15.5) kg, mean (SD) systolic BP 124.3 (14.1) mmHg, mean (SD) 73.9 (9.4) mmHg, mean (SD) triglycerides 1.28 (0.62) mmol/L, mean (SD) total cholesterol 4.88 (0.78) mmol/L, mean (SD) LDL 3.11 (0.67) mmol/L and mean (SD) HDL 1.20 (0.35) mmol/L

Why? "... a low-carbohydrate diet would produce greater weight loss at 2 years than a low-calorie, low fat diet."

What (materials)? "They followed guidelines described in Dr. Atkins' New Diet Revolution but were not provided with a copy of the book."

What (procedures)? Participants were assigned to a low-carbohydrate diet, which limited carbohydrate intake but allowed unrestricted consumption of fat and protein. For the first 12 weeks, carb intake was limited to 20g per day. After the first 12 weeks, participants gradually increased carbohydrate intake (5 g/d per week) by consuming more vegetables, a limited amount of fruits, and eventually small quantities of whole grains and dairy products, until a stable and desired weight was achieved which was in keeping with guidelines from Dr. Atkins' New Diet Revolution book. Topics in the contact sessions included self-monitoring, stimulus control, and relapse management. All participants were prescribed the same level of physical activity (principally walking), beginning at week 4, with 4 sessions of 20 minutes each and progressing by week 19 to 4 sessions of 50 minutes each. Group sessions reviewed participants' completion of their eating and activity records, as well as other skill builders.

Who provided? NR

How and where? "Face-to-face at the University of Colorado Denver, Colorado; Washington University, St. Louis, Missouri; and the University of Pennsylvania, Philadelphia, Pennsylvania."

When and how much? "All participants received comprehensive, in-person group behavioral treatment weekly for 20 weeks, every other week for 20 weeks, and then every other month for the remainder of the 2-year study period. Each treatment session lasted 75 to 90 minutes."

Strategies to improve or maintain fidelity; tailoring and modification: Overnight fasting samples, weight and height measured on calibrated scales with light clothing and no shoes, standard methods for measuring blood pressure

Extent of intervention fidelity: Group sessions reviewed participants' completion of their eating and activity records, as well as other skill builders.

Foster 2010 (Continued)

Concomitant interventions: Participants in both groups were instructed to take a daily multivitamin supplement (provided by the study).

Control diet:

Name (as reported) and brief description: Low-fat diet, participants were instructed to limit energy intake to 1200 to 1500 kcal/d for women and 1500 to 1800 kcal/day for men, with approximately 55% of calories from carbohydrates, 30% from fat and 15% from protein. Physical activity prescribed

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: N = 49 (32%) males and N = 105 (68%) females with overall mean (SD) age 44.9 (10.2) years, mean (SD) BMI 36.1 (3.46) kg/m², mean (SD) weight 103.5 (14.4) kg, mean (SD) systolic BP 124.6 (15.8) mmHg, mean (SD) 76 (9.7) mmHg, mean (SD) triglycerides 1.40 (0.83) mmol/L, mean (SD) total cholesterol 4.98 (0.85) mmol/L, mean (SD) LDL 3.21 (0.76) mmol/L and mean (SD) HDL 1.18 (0.30) mmol/L

Why? To assess whether a low-fat diet produced greater weight loss at 2 years compared to a low-carb diet

What (materials)? NR

What (procedures)? Participants were assigned to consume a low-fat diet, which consisted of limiting energy intake to 1200 to 1500 kcal/d for women and 1500 to 1800 kcal/d for men, with approximately 55% of calories from carbohydrate, 30% from fat, and 15% from protein. Participants were instructed to limit calorie intake, with a focus on decreasing fat intake. However, limiting overall energy intake (kcal/d) was the primary behavioural target.

Who provided? NR

How and where? "Face-to-face at the University of Colorado Denver, Colorado; Washington University, St. Louis, Missouri; and the University of Pennsylvania, Philadelphia, Pennsylvania."

When and how much? "All participants received comprehensive, in-person group behavioral treatment weekly for 20 weeks, every other week for 20 weeks, and then every other month for the remainder of the 2-year study period. Each treatment session lasted 75 to 90 minutes."

Strategies to improve or maintain fidelity; tailoring and modification: Overnight fasting samples, weight and height measured on calibrated scales with light clothing and no shoes, standard methods for measuring blood pressure

Extent of intervention fidelity: Group sessions reviewed participants' completion of their eating and activity records, as well as other skill builders.

Concomitant interventions: Participants in both groups were instructed to take a daily multivitamin supplement (provided by the study).

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: No

Change in BMI (kg/m²) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: No

Foster 2010 (Continued)

Change in SBP (mmHg) at \geq 12 months: No
All-cause mortality at \geq 12 months: No
Cardiovascular mortality at \geq 12 months: No
Non-fatal myocardial infarction at \geq 12 months: No
Non-fatal stroke at \geq 12 months: No
Diagnosis of type 2 diabetes mellitus at \geq 12 months: No
Change in HbA1c (%) at \geq 12 months: No
Change in LDL (mmol/L) at \geq 12 months: No
Change in HDL (mmol/L) at \geq 12 months: No
Change in non-HDL (mmol/L) at \geq 12 months: No
Change in total cholesterol (TC) (mmol/L) at \geq 12 months: No
Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at \geq 12 months: No
Participant-reported adverse effects: Yes

Methods

Review comparison(s) addressed by this study: 1
Study design: RCT, parallel, single-centre (1)
Trial registry number: NCT00868387
Total number of trial arms: 2
Year trial started: 2005
Sample size calculation: Yes
Outcome(s) used for sample size calculation: Difference in body weight
Duration of run-in period (weeks): NA
What was the duration of the weight loss phase: 12 months
What was the duration of the weight maintenance phase: NA

Frisch 2009 (Continued)

Other notes about methods: NA

Participants

Country and setting: Germany, outpatient heart centre in Bad Oeynhausen

Eligibility criteria: Participants were aged 18 to 70 with a BMI > 27 kg/m². Participants were excluded if they had a history of cardiovascular symptomatology; ischaemia, cholelithiasis, urolithiasis, insulin-dependent diabetes or a pacemaker; were pregnant or lactating; vegetarian; participated in another weight loss programme or received medical treatment for weight loss.

Type 2 diabetes at baseline: Mixed; stratified with non-T2DM since at baseline 96% in treatment and 99% in control group were not on diabetes medication and HbA1c levels were not indicative of diabetes; insulin-dependent diabetes mellitus excluded

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Mixed

Total number randomised: 200

Total attrition in trial: 35

Treatment diet
Participants randomised: 100

Participants withdrawn (voluntary): 0

Total attrition: 15

Control diet:
Participants randomised: 100

Participants withdrawn (voluntary): 0

Total attrition: 20

Baseline data treatment diet:
Randomised participants not included: None

Age (years): mean (SD) 47 (10.3)

Gender distribution (as reported): female 62/100 (62%), male 38/100 (38%)

Weight (kg): mean (SD) 100.3 (15.9)

BMI (kg/m²): mean (SD) 33.5 (3.9)

DBP (mmHg): mean (SD) 86 (8)

SBP (mmHg): mean (SD) 126 (13)

HbA1c (%): mean (SD) 5.6 (0.5)

LDL (mmol/L): mean (SD) 3.54 (0.80)

HDL (mmol/L): mean (SD) 1.49 (0.37)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.50 (0.93)

TG (mmol/L): mean (SD) 1.31 (0.56)

Frisch 2009 (Continued)

Baseline data control diet:

Randomised participants not included: None

Age (years): mean (SD) 47 (10.8)

Gender distribution (as reported): female 76/100 (76%), male 24/100 (24%)

Weight (kg): mean (SD) 98.8 (16.9)

BMI (kg/m²): mean (SD) 33.8 (4.8)

DBP (mmHg): mean (SD) 86 (8)

SBP (mmHg): mean (SD) 128 (14)

LDL (mmol/L): mean (SD) 3.56 (0.91)

HDL (mmol/L): mean (SD) 1.46 (0.37)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.54 (1.10)

TG (mmol/L): mean (SD) 1.39 (0.65)

Group differences at baseline: NR

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: LOGI (low-carbohydrate) diet. Less than 40% of total energy from carbohydrates, more than 35% from fat and 25% from protein. All participants were advised to reduce their daily energy intake by at least 500 kcal/day.

Treatment diet type (carbohydrate-fat-protein): Low-high-high

Exercise component? No

Recipients: Subjects were 62% female and aged mean (SD) 47 (10.3) years, with BMI mean (SD) 33.5 (3.9) and weight 100.3 (15.9) kgs. 45% had a metabolic syndrome.

Why? To assess whether a carbohydrate-restricted telemedically-guided weight-loss programme results in a more pronounced weight loss and influences metabolic risk markers more beneficial than a fat-restricted diet

What (materials)? Ambulatory training, diet books and an electronic scale with Bluetooth technology

What (procedures)? Intervention diet consisted of less than 40% of total energy intake (% energy) from carbohydrates, more than 35% energy from fat, and 25% energy from protein. Weekly nutrition education programme and dietary counselling by telephone, and had to transfer actual body weight data to our clinic weekly with added Bluetooth® technology by mobile phone.

Who provided? Dietitian

How and where? Telephonic (individual) sessions

Frisch 2009 (Continued)

When and how much? Weekly actual body weight was sent through mobile phones together with weekly education and dietary counselling by phone.

Strategies to improve or maintain fidelity; tailoring and modification: Regular weekly calls with the dietitian. Dietary compliance was assessed using a 3-day validated food record. Weight sent via Bluetooth

Extent of intervention fidelity: NR

Concomitant interventions: Of the intervention participants 24% were taking anti-hypertensive drugs, 6% lipid-lowering drugs and 4% anti-diabetic drugs.

Control diet:

Name (as reported) and brief description: DGE (high-carbohydrate) diet. More than 55% of total energy from carbohydrates, less than 30% from fat and 15% from protein. All participants were advised to reduce their daily energy intake by at least 500 kcal/day.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Subjects were 76% female and aged mean (SD) 47 (10.8) years, with BMI mean (SD) 33.8 (4.8) and weight 98.8 (16.9) kgs; 31% had a metabolic syndrome.

Why? NR

What (materials)? Ambulatory training, diet books and an electronic scale with Bluetooth technology

What (procedures)? The control diet consisted of more than 55% energy from carbohydrates, less than 30% energy from fat, and 15% energy from protein together with weekly nutrition education programme and dietary counselling by telephone, and had to transfer actual body weight data to our clinic weekly with added Bluetooth® technology by mobile phone.

Who provided? Dietitian

How and where? Telephonic (individual) sessions

When and how much? Weekly actual body weight was sent through mobile phones together with weekly education and dietary counselling by phone.

Strategies to improve or maintain fidelity; tailoring and modification: Regular weekly calls with the dietitian. Dietary compliance was assessed using a 3-day validated food record. Weight sent via Bluetooth

Extent of intervention fidelity: NR

Concomitant interventions: Of control participants 31% were taking anti-hypertensive drugs, 4% lipid-lowering drugs and 1% anti-diabetic drugs.

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Atkins diet. Aimed for 20 g/d or less of carbohydrates for induction of 2 to 3 months and 50 g/d for the 'ongoing weight loss' phase, ad libitum energy prescription

Treatment diet type (carbohydrate-fat-protein): Very low8-12w to low40-44w-unclear-unclear

Exercise component? No

Recipients: Overweight or obese premenopausal women, aged mean (SD) 42 (5) years with BMI mean (SD) 32 (4) and weight mean (SD) 86 (13) kg, with or without metabolic syndrome, n (%) 22/77 (29%)

Why? Low-carbohydrate diets ad libitum diets may be at least as effective as traditional low-fat, high-carbohydrate diets for weight loss up to one year. The evidence to date is limited.

What (materials)? Dr Atkins' New Diet Revolution ([Atkins 2002](#)).

What (procedures)? Participants in this diet group aimed for the consumption of 20 g/d or less of carbohydrate for 'induction' (usually 2-3 months) and 50 g/d or less of carbohydrate for the subsequent 'ongoing weight loss' phase. Participants were assigned their diet book, attended regular classes covering the contents of the book and were administered unannounced dietary intake and energy expenditure questionnaires.

Who provided? A registered dietitian led the classes and covered a portion of the book's contents per session so it would be complete at the end of the contact period. Unannounced dietary and exercise data were collected by persons trained and certified by the Nutrition Coordinating Centre.

Gardner 2007 (Continued)

How and where? Class sessions were held face-to-face and in groups, location NR. Unannounced dietary and exercise data were collected by telephone.

When and how much? Class sessions were one hour each and occurred every week for eight weeks. Unannounced dietary and exercise data were collected at baseline and at 2, 6 and 12 months. This entailed recall of three days (two weekdays and one weekend day, preferably non-consecutive) of dietary intake as well as seven days of physical activity.

Strategies to improve or maintain fidelity; tailoring and modification: Strategies included email and telephone reminders for appointments, email or telephone contact from staff between the 2- and 6-month and between the 6- and 12-month data collection points, and incentive payments of \$25, \$50, and \$75 for completing the 2-, 6-, and 12-month data collection, respectively. A 'Food Amounts Booklet' was used to assist participants with portion size estimation during dietary recalls. Unannounced dietary and exercise recalls, group sessions, measurement of body weight as part of study outcomes

Extent of intervention fidelity: Dietary adherence scores calculated as the difference between reported and recommended daily carbohydrate intake (≤ 20 g carbohydrate per day during the first two months; and ≤ 50 g carbohydrate per day for the subsequent 10 months), using the average of three non-consecutive 24-h dietary recalls at each time point. A lower score reflects better adherence. Adherence score, means (SD): at 2 months, 35.2 (32.7); at 6 months, 62.6 (64.7); at 12 months, 85.8 (70.5). In all 4 diet groups, 85% to 89% of participants attended at least 75% of their assigned classes (≥ 6 of 8). Attendance was not different by diet group ($P = 0.68$).

Concomitant interventions: Participants on antihypertensive medications whose blood pressure was stable, as well as those on treatment for hyperthyroidism vs "were not taking medications for cardiac risk factors"?

Control diet:

Name (as reported) and brief description: LEARN diet. Prudent diet that included 55 to 60% of energy from carbohydrates and less than 10% energy from saturated fat, unspecified caloric restriction, increased exercise

Control diet type (carbohydrate-fat-protein): Balanced-unclear-unclear

Exercise component? Yes

Recipients: Overweight or obese premenopausal women, aged mean (SD) 40 (7) years with BMI mean (SD) 31 (4) and weight mean (SD) 85 (14) kg, with or without metabolic syndrome, n (%) 29/79 (37)

Why? This diet is based on national American guidelines. Such national guidelines have been challenged by proponents of low-carbohydrate diets, but limited evidence is currently available.

What (materials)? Participants were instructed to follow a prudent diet that included 55% to 60% energy from carbohydrate and less than 10% energy from saturated fat, caloric restriction, increased exercise, and behaviour modification strategies. The LEARN program is intended to be a 16-week programme and, therefore, the 8 weeks of guidance in this study. Participants were assigned to a diet book (the LEARN Manual for Weight Management).

What (procedures)? Participants were assigned their diet book, attended regular classes covering the contents of the book and were administered unannounced dietary intake and energy expenditure questionnaires. Participants were instructed to follow a prudent diet that included 55% to 60% energy from carbohydrate and less than 10% energy from saturated fat, caloric restriction, increased exercise, and behaviour modification strategies.

Who provided? A registered dietitian led the classes and covered a portion of the book's contents per session so it would be complete at the end of the contact period. Unannounced dietary and exercise data were collected by persons trained and certified by the Nutrition Coordinating Centre.

How and where? Class sessions were held face-to-face and in groups, location NR. Unannounced dietary and exercise data were collected by telephone.

When and how much? Class sessions were one hour each and occurred every week for eight weeks. Since the LEARN program spans 16 weeks, therefore these sessions reflected an accelerated timespan.

Gardner 2007 (Continued)

Unannounced dietary and exercise data were collected at baseline and at 2, 6 and 12 months. This entailed recall of three days (two weekdays and one weekend day, preferably non-consecutive) of dietary intake as well as seven days of physical activity.

Strategies to improve or maintain fidelity; tailoring and modification: Strategies included email and telephone reminders for appointments, email or telephone contact from staff between the 2- and 6-month and between the 6- and 12-month data collection points, and incentive payments of \$25, \$50, and \$75 for completing the 2-, 6-, and 12-month data collection, respectively. A 'Food Amounts Booklet' was used to assist participants with portion size estimation during dietary recalls. Unannounced dietary and exercise recalls, group sessions, measurement of body weight as part of study outcomes

Extent of intervention fidelity: Dietary adherence scores could not be calculated due to the multiple dimensions of the intervention programme's recommended goals. In all 4 diet groups, 85% to 89% of participants attended at least 75% of their assigned classes (≥ 6 of 8). Attendance was not different by diet group ($P = 0.68$).

Concomitant interventions: Participants on antihypertensive medications whose blood pressure was stable, as well as those on treatment for hyperthyroidism vs "were not taking medications for cardiac risk factors"?

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

HDL (mmol/L): mean (SD) 1.36 (0.32)

Non-HDL (mmol/L): mean (SD) 4.19 (0.87)

TC (mmol/L): mean (SD) 5.56 (0.93)

TG (mmol/L): mean (SD) 1.23 (0.66)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: DBP, SBP, LDL, HDL, non-HDL, total cholesterol and triglycerides baseline values are not for all randomised (missing: intervention 19/72; control 21/75). Last phrase of exclusion criteria in Goni et al 2018 reads strangely.

Goni 2018 (Continued)

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Moderately high protein diet, 40% carbohydrates, 30% protein and 30% fat. Restriction of 30% of total energy. Energy requirements were individually evaluated from resting energy expenditure.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: Subjects were 66.7% female and aged mean (SD) 45.6 (11.2) years, with BMI mean (SD) 31.7 (3.6) and weight of 88.5 (13.2) kgs.

Why? The hypothesis of the present study is that part of the interindividual variability in relation to the success of certain weight loss treatments is based on gene-diet interactions. Depending on the composition of the diet and the genotype of each individual, it is more or less easy to reduce and maintenance body weight.

What (materials)? Participants received detailed information from trained nutritionists regarding feeding schedules, portion sizes, and cooking methods.

What (procedures)? Moderately-high protein diet: 40% of total energy from carbohydrates, 30% from protein, and 30% from fat for 16 weeks. Habitual dietary intake at baseline was evaluated by a previously validated semi-quantitative food frequency questionnaire. Detailed information from trained nutritionists regarding feeding schedules, portion sizes, and cooking methods

Who provided? Dietitian

How and where? Face-to-face sessions, location NR

When and how much? 16 weeks

Strategies to improve or maintain fidelity; tailoring and modification: Compliance analysis to the recommended diet of the participants was conducted taking into account a three-day weighed food record (two weekdays and one weekend day) at two times: the eighth week and at the end of the intervention period (the 16th week). The adherence to the diet was graded by trained dietitians during each visit of the intervention according to the following scale: 0: failure to follow the diet at any time (poor adherence); 1: follow-up across weekdays but not during weekends (regular adherence); 2: occasionally exceeded from recommendations (good adherence); and 3: continuous follow-up (very good adherence). Also, during the 4 months of nutritional intervention, nutritionists conducted motivational telephone calls with each participant in order to increase the adherence to the dietary advice based on previous trials.

Extent of intervention fidelity: The adherence to the diets was graded by trained dietitians during each visit of the intervention according to a scale. In the moderately-high protein diet group, the targets of macronutrient intakes during the intervention were achieved.

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Low-fat diet, 60% carbohydrates, 18% protein and 22% fat. Restriction of 30% of total energy. Energy requirements were individually evaluated from resting energy expenditure.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Subjects were 68% female and aged mean (SD) 47.5 (8.6) years, with BMI mean (SD) 32.1 (3.8) and weight of 88.8 (13.3) kgs.

Goni 2018 (Continued)

Why? NR

What (materials)? Participants received detailed information from trained nutritionists regarding feeding schedules, portion sizes, and cooking methods.

What (procedures)? low-fat diet: 60% of total energy from carbohydrates, 18% from protein, and 22% from fat for 16 weeks

Who provided? Dietitian

How and where? Face-to-face sessions, location NR

When and how much? 16 weeks

Strategies to improve or maintain fidelity; tailoring and modification: Compliance analysis to the recommended diet of the participants was conducted taking into account a three-day weighed food record (two weekdays and one weekend day) at two times: the eighth week and at the end of the intervention period (the 16th week). TC (mmol/L): mean (SD) 4.7 (0.91)

TG (mmol/L): mean (SD) 1.0 (0.60)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Values reported as mean (95% CI) were converted to mean (SD).

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein (HP) diet, providing 32% protein, 41% carbohydrate and 25% fat. Low-GI foods were recommended, saturated fat was < 10% TE. Walking (30 min most days) prescribed. Energy prescription of 5600 kJ/day

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: N = 36 women with mean (95%CI) age 22.4 (21.6 to 23.2) years, mean (95% CI) weight 95.2 (91.0 to 99.3) kg, mean (95% CI) BMI 34.1 (32.7 to 35.5) kg/m²

Why? Higher-protein (HP) diets have been reported as effective for weight loss in middle-aged obese adults. Enhanced satiety with higher protein diets may be helpful for young women as hunger and disinhibition are reported to be problematic in this population. These diets tend to be more nutrient-dense and provide greater iron, a nutrient often under-consumed in young women and for which requirements are higher due to menstrual losses.

What (materials)? Participants were provided with kitchen scales, daily checklists, recipe ideas and money vouchers (AUD \$20) at baseline, three, six, nine and 12 months to assist with food measurement, cooking healthy meals and dietary compliance. Participants also received a validated activity diary.

What (procedures)?

The HP diet provided 32% protein (107 g/day), 41% carbohydrate (138 g/day) and 25% fat (38 g/day) Low-glycaemic index (< 55) carbohydrate foods were recommended. Diets were matched for energy (5600 kJ/day), saturated fat (< 10% daily energy), dietary fibre and calcium. Total fat was similar (HP: 37.9; HC: 31.9 g/day). Limited alcohol intake (≤ 20 g/week; ~1% of daily energy) was permitted. HP and HC participants consumed 300 and 80 g (raw weight) of meat/day, respectively, with set amounts of red and white meats prescribed. 27 dietetic and behaviour modification sessions: weekly from 0 to 3 months, fortnightly from 3 to 6 months, then monthly from 6 to 12 months. 10-module weight-management programme (Bodylines). Participants were prescribed an identical exercise programme (30 min walking most days) with expenditure estimated using a validated activity diary.

Who provided? NR

How and where? Face-to-face sessions, location, NR

When and how much? Weekly until 3 months, fortnightly between 3 and 6 months then monthly until 12 months

Strategies to improve or maintain fidelity; tailoring and modification: Dietary intake was estimated using 3-day food records. Twenty-four hour urine collections provided urea/creatinine ratio (UCR) to monitor recent protein intake.

Extent of intervention fidelity: Reported intakes were close to the dietary prescription but HC tended to report lower energy intake (1148 kJ less in 12-month completers). Iron intake was significantly higher on HP [HP: 12.9 (11.0 to 14.9); HC: 8.5 (7.4 to 9.6) mg/day; P < 0.001 in 6-month completers].

Concomitant interventions: NR

Griffin 2013 (Continued)

Control diet:

Name (as reported) and brief description: High-carbohydrate (HC) diet, providing 20% protein, 58% carbohydrate and 21% fat. Low-GI foods were recommended, saturated fat was < 10% TE. Walking (30 min most days) prescribed. Energy prescription of 5600 kJ/day

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: N = 36 women with mean (95% CI) age 22.5 (21.7 to 23.3) years, mean (95% CI) weight 94.3 (89.3 to 99.3) kg, mean (95% CI) BMI 33.8 (32.1 to 35.5) kg/m²

Why? NR

What (materials)? Participants were provided with kitchen scales, daily checklists, recipe ideas and money vouchers (AUD \$20) at baseline, three, six, nine and 12 months to assist with food measurement, cooking healthy meals and dietary compliance. Participants also received a validated activity diary.

What (procedures)?

Participants were prescribed a HC diet providing 20% protein (67 g/day), 58% carbohydrate (191 g/day) and 21% fat (32 g/day). Low-glycaemic index (< 55) carbohydrate foods were recommended. Diets were matched for energy (5600 kJ/day), saturated fat (< 10% daily energy), dietary fibre and calcium. Total fat was similar (HP: 37.9; HC: 31.9 g/day). Limited alcohol intake (≤ 20 g/week; ~1% of daily energy) was permitted. HP and HC participants consumed 300 and 80 g (raw weight) of meat/day, respectively, with set amounts of red and white meats prescribed. Participants were prescribed an identical exercise programme (30-min walking most days) with expenditure estimated using a validated activity diary. 27 dietetic and behaviour modification sessions: weekly from 0 to 3 months, fortnightly from 3 to 6 months, then monthly from 6 to 12 months. HC: red meat 1 time/week; white meat 4 times/week. 10-module weight-management programme (Bodylines). A standard recommendation of walking 30 min on most days was prescribed to all.

Who provided? NR

Other notes about participants: HbA1c mmol/mol baseline values also reported: intervention mean (SD) 58.5 (10.2) mmol/mol; control mean (SD) 55.6 (8.0) mmol/mol

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate diet, energy content with 50% from fat, 20% from carbohydrates and 30% from protein. Energy content of 6694 kJ/day for women or 7531 kJ/day for men

Treatment diet type (carbohydrate-fat-protein): Low-high-high

Exercise component? No

Recipients: N = 14 men and N = 16 women, mean (SD) age 61.2 (9.5) years, mean (SD) weight 91.4 (19) kg, mean (SD) BMI 31.6(5.0) kg/m², mean (SD) duration of known diabetes of 9.8 (5.5) years

Why? High-fat diet (i.e. with low carbs) would improve glycaemic control more efficiently than the traditional low-fat diet (LFD).

What (materials)? Menus for 1 week were provided to the participants as meal suggestions by the dietitian. Weighing scales and notebooks from the organisers with which to weigh and record all food items that were consumed during these periods

What (procedures)? The LCD had an energy content where 50 energy per cent (E%) was from fat, 20 E% was from carbohydrate and 30 E% was from protein. Both diets had an energy content of 6694 kJ/day (1600 kcal/day) for women or 7531 kJ/day (1800 kcal/day) for men. 4 group meetings of 60 mins each for the first year. Group sessions on which food items to choose from and suitable recipes

Who provided? Dietitian provided recipes and a menu for one week. Two different physicians conducted the group session where participants learnt which foods to choose from.

How and where? Face-to-face at two primary healthcare centres in the cities of Motala and Borensberg, located in southeast Sweden

When and how much? Four group meetings with a duration of 60 min each for the first year; no further group meetings during the remaining 12 months were held. Group sessions were given at baseline, and

Guldbrand 2012 (Continued)

2, 6 and 12 months by two different physicians. A dietitian was available consecutively during the trial for questions from the participants.

Strategies to improve or maintain fidelity; tailoring and modification: Diet records were also performed at these four visits, with one additional recording at 3 months. The diet records were conducted during 3 consecutive days, of which 1 day was a Saturday or a Sunday.

Extent of intervention fidelity: NR

Concomitant interventions: Of the intervention participants the total insulin dose was 42 (65), metformin (mg) 1375 (950), glibenclamide (mg) 1.1 (2.6), simvastatin (mg) 19 (18) and atorvastatin (mg) 2 (5).

Control diet:

Name (as reported) and brief description: Low-fat diet, energy content with 30% from fat (< 10% from saturated fat), 55 to 60% from carbohydrates and 10 to 15% from protein. Energy content of 6694 kJ/day for women or 7531 kJ/day for men

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: NR

Why? NR

What (materials)? Menus for 1 week were provided to the participants as meal suggestions by the dietitian. Weighing scales and notebooks from the organisers with which to weigh and record all food items that were consumed during these periods

What (procedures)? The LFD had a nutrient composition that was similar to that traditionally recommended for the treatment of type 2 diabetes in Sweden, with 30 E% from fat (less than 10 E% from saturated fat), 55–60 E% from carbohydrate and 10–15 E% from protein. 4 group meetings of 60 mins each for the first year

Who provided? Dietitian provided recipes and a menu for one week. Two different physicians conducted the group session where participants learnt which foods to choose from.

How and where? Face-to-face at two primary healthcare centres in the cities of Motala and Borensberg, located in southeast Sweden

When and how much? Four group meetings with a duration of 60 min each for the first year; no further group meetings during the remaining 12 months were held. Group sessions were given at baseline, and 2, 6 and 12 months by two different physicians. A dietitian was available consecutively during the trial for questions from the participants.

Strategies to improve or maintain fidelity; tailoring and modification: Diet records were also performed at these four visits, with one additional recording at 3 months. The diet records were conducted during 3 consecutive days, of which 1 day was a Saturday or a Sunday.

Extent of intervention fidelity: NR

Concomitant interventions: Of the control participants the total insulin dose was 39 (51), metformin (mg) 1435 (946), glibenclamide (mg) 0.4 (1.9), simvastatin (mg) 19 (17) and atorvastatin (mg) 2 (5).

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 4.85 (0.66)

TG (mmol/L): mean (SD) 1.14 (0.49)

Haufe 2013 (Continued)

Baseline data control diet:

Randomised participants not included: 36/86 (except for age, weight and BMI 32/86)

Age (years): mean (SD) 45 (9)

Gender distribution (as reported): female 40/50, male 10/50

Weight (kg): mean (SD) 93 (19)

BMI (kg/m²): mean (SD) 33.5 (4.3)

DBP (mmHg): NR

SBP (mmHg): NR

HbA1c (%): NR

LDL (mmol/L): mean (SD) 3.15 (0.89)

HDL (mmol/L): mean (SD) 1.38 (0.56)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 4.9 (0.95)

TG (mmol/L): mean (SD) 1.20 (0.63)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: All baseline characteristics are reported by trial arm and intrahepatic lipids; these were combined to give characteristics by trial arm only.

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Reduced-carbohydrate diet. Aimed at achieving ≤ 90 g/d of carbohydrates, 0.8 g protein per kg body weight and a minimum of 30% fat. Total energy prescription of 30% less than baseline intake (to a minimum of 1200 kcal/day)

Treatment diet type (carbohydrate-fat-protein): Low-unclear-high

Exercise component? No

Recipients: Participants were 84.6% female, aged 43.15 (8.67) years, with BMI 33.38 (4.24) and weight 92.85 (14.81) kg

Why? Weight reduction through caloric restriction decreases hepatic fat up to 12 months and improves insulin sensitivity while preventing type 2 diabetes.

What (materials)? NR

What (procedures)? Participants followed a reduced energy diet with nutritional counselling to a reduced-carbohydrate diet, with regular group sessions and analysis of seven-day food protocols.

Who provided? Group sessions and individual counselling, with food protocol analysis, were run by nutritionists.

How and where? Face-to-face group sessions and individual face-to-face sessions, location NR. Telephonic check-ins on weight changes were done in the weight maintenance phase.

Haufe 2013 (Continued)

When and how much? The active intervention duration was six months, with follow-up after weight maintenance of between 17 and 36 months [from 18 Haufe 2011]. Group sessions occurred on a weekly basis throughout the active weight loss phase, with individual counselling occurring every two months in this phase. An analysis of seven-day food protocol was conducted at every individual counselling. No active intervention occurred in the weight maintenance phase.

Strategies to improve or maintain fidelity; tailoring and modification: Group sessions, follow-up measurement of body weight, keeping of food protocols, adherence monitoring in individual sessions

Extent of intervention fidelity: The authors reported that participants adhered to their assigned intervention.

Concomitant interventions: "They [participants] ingested no medications."

Control diet:

Name (as reported) and brief description: Reduced-fat diet. Aimed at achieving a fat content of $\leq 20\%$ of total energy intake, 0.8 g protein per kg body weight and the remaining energy content provided by carbohydrates. Author reported via email that this group ingested 53.7% carbohydrates. Total energy prescription of 30% less than baseline intake (to a minimum of 1200 kcal/day)

Control diet type (carbohydrate-fat-protein): Balanced-low-high

Exercise component? No

Recipients: Participants were 80.0% female, aged 45.08 (8.96) years, with BMI 32.98 (3.55) and weight 92.32 (17.2) kg.

Why? Low-fat caloric restriction diets reduce the hepatic fat content in humans.

What (materials)? NR

What (procedures)? Participants followed a reduced energy diet with nutritional counselling to a reduced-fat diet, with regular group sessions and analysis of seven-day food protocols.

Who provided? Group sessions and individual counselling, with food protocol analysis, were run by nutritionists.

How and where? Face-to-face group sessions and individual face-to-face sessions, location NR. Telephonic check-ins on weight changes were done in the weight maintenance phase.

When and how much? The active intervention duration was six months, with follow-up after weight maintenance of between 17 and 36 months [from 18 Haufe 2011]. Group sessions occurred on a weekly basis throughout the active weight loss phase, with individual counselling occurring every two months in this phase. An analysis of seven-day food protocol was conducted at every individual counselling. No active intervention occurred in the weight maintenance phase.

Strategies to improve or maintain fidelity; tailoring and modification: Group sessions, follow-up measurement of body weight, keeping of food protocols, adherence monitoring in individual sessions

Extent of intervention fidelity: The authors reported that participants adhered to their assigned intervention.

Concomitant interventions: "They [participants] ingested no medications."

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: Yes

Haufe 2013 (Continued)

Change in BMI (kg/m²) at ≥ 12 months: Yes

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: No

Change in SBP (mmHg) at ≥ 12 months: No

All-cause mortality at ≥ 12 months: No

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: No

Change in LDL (mmol/L) at ≥ 12 months: Yes

Change in HDL (mmol/L) at ≥ 12 months: Yes

Change in non-HDL (mmol/L) at ≥ 12 months: No

Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: Yes

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: Yes

Participant-reported adverse effects: No

Notes

Participants

Country and setting: UK, outpatient hospital diabetic clinic in Oxford

Eligibility criteria: Participants were newly-diagnosed diabetics under 65 years who did not suffer from co-existing major illness and did not need insulin therapy immediately. Participants were excluded if they had a history of, or current, endocrine disease, myocardial infarction or neurological deficit after a cerebrovascular accident; or were currently suffering from liver disease, however, those with a past history of liver disease were not excluded.

Type 2 diabetes at baseline: Yes

Impaired glucose tolerance at baseline: No

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Mixed

Total number randomised: 93

Total attrition in trial: NR

Treatment diet
Participants randomised: 54

Participants withdrawn (voluntary): NR

TG (mmol/L): mean (SE) 1.59 (0.12)

Group differences at baseline: Yes

Characteristic(s) with significant group difference and relevant statistic: characteristic 1: number of overweight participants ($P < 0.02$)

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate (LC) diet, 20% protein, 40% carbohydrate, 40% total fat (28% saturated and monounsaturated and 12% PUFA). Energy prescription of 6300 kJ a day

Treatment diet type (carbohydrate-fat-protein): Low-high-balanced

Exercise component? No

Recipients: Newly-diagnosed diabetics, 40.7% female, aged mean 53 (range 22 to 65) years with weight mean 76.4 (range 51 to 99) kg. Having raised baseline levels of cholesterol, triglycerides, glucose and insulin

Why? To investigate the effects of a low-carb diet compared to low-fat diet for development of cardiovascular risk factors. Low-carbohydrate diets are normally prescribed to diabetic patients in the Western world.

What (materials)? NR

What (procedures)? Participants were instructed to consume a low-carbohydrate diet, and were seen regularly to reinforce dietary advice. Dietary counselling at each visit

Who provided? Dietitians met with participants to reinforce dietary advice at follow-up visits

How and where? Meeting with dietitians occurred face-to-face at the diabetic clinic from which participants were recruited.

Hockaday 1978 (Continued)

When and how much? The duration of the intervention was one year. Patients were seen by dietitians for the reinforcement of dietary advice after one month, and then every three months.

Strategies to improve or maintain fidelity; tailoring and modification: Meetings at one month and at three-month intervals thereafter to repeat dietary advice; weigh-in at one month and one year

Extent of intervention fidelity: Authors reported only that participants varied in their cooperation.

Concomitant interventions: Participants did not require treatment with insulin or another oral hypoglycemic medication during the study.

Control diet:

Name (as reported) and brief description: Modified-fat high-carbohydrate (MF) diet, 20% protein, 54% carbohydrate, 26% total fat (10% saturated and monounsaturated and 16% PUFA). Energy prescription of 6300 kJ a day

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Newly-diagnosed diabetics, 48.7% female, aged mean 50 (range 24 to 65) years with weight mean 82.2 (range 56 to 114) kg. Having raised baseline levels of cholesterol, triglycerides, glucose and insulin

Why? The Japanese, Trappists and Yemenite Jews consume diets high in carbohydrates; these populations tend to have lower serum lipids and lower prevalence of ischaemic heart disease - both in diabetics as well as the general population.

What (materials)? NR

What (procedures)? Participants were instructed to consume a modified-fat diet, and were seen regularly to reinforce dietary advice.

Who provided? Dietitians met with participants to reinforce dietary advice at follow-up visits.

How and where? Meeting with dietitians occurred face-to-face at the diabetic clinic from which participants were recruited.

When and how much? The duration of the intervention was one year. Patients were seen by dietitians for the reinforcement of dietary advice after one month, and then every three months.

Strategies to improve or maintain fidelity; tailoring and modification: Meetings at one month and at three-month intervals thereafter to repeat dietary advice; weigh-in at one month and one year

Extent of intervention fidelity: Authors reported only that participants varied in their cooperation.

Concomitant interventions: Participants did not require treatment with insulin or another oral hypoglycemic medication during the study.

Participants

Country and setting: Australia, outpatient research organisation in Adelaide. Sample food packs or 20 AUD vouchers were given to participants at inception, 12 and 26 weeks.

Eligibility criteria: Participants were women aged 40 to 70 years with a BMI > 27 kg/m²; women were postmenopausal (absence of periods for 12 months and follicular-stimulating hormone concentration > 20 U/L). Participants were excluded if their body weight was > 140 kg; had a total hip BMD t-score less than -2.0 or a t-score less than -1.0 with a history of low-trauma peripheral or spine fracture; took hormone-replacement therapy, bisphosphonates, steroids, diuretics, calcium or vitamin D; had parathyroid disease, a vitamin D concentration < 60 nmol/L with secondary hyperparathyroidism; significant diseases including unstable metabolic, cardiac, gastrointestinal or renal conditions or malignancies.

Type 2 diabetes at baseline: Unclear; stratified with non-T2DM since unstable metabolic disease was an exclusion criterion.

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Female

TG (mmol/L): NR

Group differences at baseline: Yes

Characteristic(s) with significant group difference and relevant statistic: characteristic 1: 24-hour urea excretion (P < 0.02); intervention vs control

Other notes about participants: Baseline BMI value in intervention group was for n = 163, instead of n = 164.

 Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein diet. Protein/fat/carbohydrate recommended at 32/24/44% of total energy. The diet provided ~5500 kJ/d.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: N = 164 women with a mean (SE) age 59.5 (0.42) years, mean (SE) BMI 34.0 (0.43) kg/m²; N = 12 of 164 (7.3%) were smokers and consumed mean (SE) 355 (36) grams of alcohol per week.

Why? To assess if a high-protein (HP) weight-loss diet was detrimental to bone health compared with a high-normal-protein (HNP) diet matched for energy.

What (materials)? Sample food packs or \$20 vouchers were provided to participants at study commencement and 12 and 26 wks. Participants were instructed to record their dietary intakes by using a protein counter and checklist.

What (procedures)? The HP diet plan contained less or equal to 32% of calories as protein (> 90 g/d) with low saturated and total fat (< 10% and < 30%, respectively). The diets were isocaloric and provided roughly 5500 kJ/d. During group sessions, participants received general information regarding diet and lifestyle self-management. Subjects were made aware of the benefits of exercise although there was no formal exercise programme. Participants were instructed to record their dietary intakes by using a protein counter and checklist which were collected at each group session.

Jesudason 2013 (Continued)

Who provided? Dietitian

How and where? "Participants were offered phone support with a dietitian, individual consultations, and monthly phone or email contact support as well as monthly face-to-face groups sessions."

When and how much? Participants received monthly group dietetic education and support for the first 6 mo and then every 3 mo for the next 18 mo. Individual or telephonic consultations were also offered monthly. Change in bone mineral density (BMD) of the total hip was assessed at 12 and 24 mo.

Strategies to improve or maintain fidelity; tailoring and modification: "Compliance to the HP diet was assessed by reference to the blood urea nitrogen and 24-h urine for urea nitrogen excretion. Protein-compliance checklists were collected from each participant at each group session."

Extent of intervention fidelity: mean (SE) blood urea nitrogen at 12 months 17.9 (0.3) mg/dL and at 24 months 17.(0.6) mg/dL; mean (SE) urine urea nitrogen at 12 months 11.8 (0.3) g/24 h and at 24 months 12.0 (0.3) g/24 h

Concomitant interventions: Women were ineligible if they were taking hormone-replacement therapy, bisphosphonates, steroids, diuretics, calcium, or vitamin D. Selective serotonin reuptake inhibitor drugs were allowed.

Control diet:

Name (as reported) and brief description: High-normal protein diet. Protein/fat/carbohydrate recommended at 22/23/55. The diet provided ~5500 kJ/d.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-high

Exercise component? No

Recipients: N = 159 women with a mean (SE) age 59.4 (0.4) years, mean (SE) BMI 33.4 (0.4) kg/m², N = 8 of 159 (5.0%) were smokers and consumed mean (SE) 449 (56) grams of alcohol per week.

Why? To evaluate whether a lower protein diet has fewer detrimental effects on bone health

What (materials)? Sample food packs or \$20 vouchers were provided to participants at study commencement and 12 and 26 wk. Participants were instructed to record their dietary intakes by using a protein counter and checklist.

What (procedures)? The normal protein (HNP) diet plan had less or equal to 22% of calories as protein (< 80 g/d), similar fat, and 55% of energy from low-glycemic index carbohydrates. The diets were isocaloric and provided roughly 5500 kJ/d. During group sessions, participants received general information regarding diet and lifestyle self-management. Subjects were made aware of the benefits of exercise although there was no formal exercise programme. Participants were instructed to record their dietary intakes by using a protein counter and checklist which were collected at each group session.

Who provided? Dietitian

How and where? Participants were offered phone support with a dietitian, individual consultations, and monthly phone or email contact support as well as monthly face-to-face group sessions.

When and how much? Participants received monthly group dietetic education and support for the first 6 mo and then every 3 mo for the next 18 mo. Individual or telephonic consultations were also offered monthly. Change in bone mineral density (BMD) of the total hip was assessed at 12 and 24 mo.

Strategies to improve or maintain fidelity; tailoring and modification: "Compliance to the HP diet was assessed by reference to the blood urea nitrogen and 24-h urine for urea nitrogen excretion. Protein-compliance checklists were collected from each participant at each group session."

Extent of intervention fidelity: mean (SE) blood urea nitrogen at 12 months 14.8 (0.1) mg/dL and at 24 months 14.8 (0.6) mg/dL; mean (SE) urine urea nitrogen at 12 months 9.3 (0.3) g/24 h and at 24 months 9.9 (0.3) g/24 h

Jesudason 2013 (Continued)

Concomitant interventions: Women were ineligible if they were taking hormone-replacement therapy, bisphosphonates, steroids, diuretics, calcium, or vitamin D. Selective serotonin reuptake inhibitor drugs were allowed.

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

160

Josse 2011 (Continued)

Study design: RCT, parallel, single-centre (1)

Trial registry number: NCT00710398

Total number of trial arms: 3

Year trial started: 2008

Sample size calculation: No

Outcome(s) used for sample size calculation: NA

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 16 weeks

What was the duration of the weight maintenance phase: NA

Other notes about methods: NA

Participants

Country and setting: Canada, outpatient university centre. Participants were provided with a study drink, appropriate for their diet, before exercise and immediately following exercise on a daily basis.

Eligibility criteria: Participants were premenopausal women who were overweight and obese (defined as BMI 27 to 40 kg/m²) aged between 19 and 45 years; who consumed low levels of dairy, had a sedentary lifestyle, regular menstrual cycle, did not take vitamin or mineral supplements and were otherwise healthy as confirmed by short medical screening questionnaire. Participants were excluded if they had any of the conditions comprising the short medical screening questionnaire: the presence of metabolic risk factors; heart or other organ disease; orthopaedic injury which would affect exercise; gastrointestinal disease; diagnosed dairy protein allergy; diagnosed lactose intolerance or use of prescription medication.

Type 2 diabetes at baseline: No

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Female

Total number randomised: 90

Total attrition in trial: NR

Treatment diet

Participants randomised: 31

Participants withdrawn (voluntary): 3

Total attrition: NR

Control diet:

Participants randomised: 31

Participants withdrawn (voluntary): 0

Total attrition: NR

Baseline data treatment diet:

Randomised participants not included: 1/31

Age (years): mean (SE) 30 (1)

Josse 2011 (Continued)

Gender distribution (as reported): female 100%, male 0%

Weight (kg): mean (SE) 86.7 (2.2)

BMI (kg/m²): mean (SE) 31.4 (0.6)

DBP (mmHg): NR

SBP (mmHg): NR

HbA1c (%): mean (SE) 5.4 (0.1)

LDL (mmol/L): mean (SE) 2.77 (0.13)

HDL (mmol/L): mean (SE) 1.43 (0.05)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SE) 4.67 (0.15)

TG (mmol/L): mean (SE) 1.00 (0.07)

Baseline data control diet:

Randomised participants not included: 1/31

Age (years): mean (SE) 26 (1)

Gender distribution (as reported): female 100%, male 0%

Weight (kg): mean (SE) 85.2 (2.0)

BMI (kg/m²): mean (SE) 31.8 (0.6)

DBP (mmHg): NR

SBP (mmHg): NR

HbA1c (%): mean (SE) 5.4 (0.1)

LDL (mmol/L): mean (SE) 2.58 (0.09)

HDL (mmol/L): mean (SE) 1.39 (0.05)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SE) 4.48 (0.11)

TG (mmol/L): mean (SE) 1.11 (0.07)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Baseline data for intervention 14/30, control 13/30 and third arm 12/30 for HbA1c, total cholesterol, LDL, HDL and TG. Of the intervention arm 3 additional participants withdrew, and from the third trial arm 6 additional participants withdrew.

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein high-dairy (HPHD) diet. Consisting of 40% carbohydrate, 30% fat and 30% protein. Aerobic exercise 7 days a week to expend 250 kcal/day. Prescribed energy was maintenance energy requirements reduced by 500 kcal/d.

Josse 2011 (Continued)

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: NR

Why? Higher-protein, lower-carbohydrate, energy-restricted diets have been shown to help offset the lean mass loss observed with conventions (-55% energy intake carbohydrate diets). The study was designed such that the HPDH group consumed twice the amount of protein (and lower carbohydrate) than the other 2 groups and twice the amount of dairy.

What (materials)? Individualised plan outlining their required macronutrients intake in grams (corresponding to their new energy requirements); 2 study drinks/d (one immediately post-exercise and another drink at least 5 hours before or after exercise); Splenda-sweetened 1% chocolate milk). All dairy products required during the study period (1% artificially sweetened chocolate milk, white milk, yoghurt, cheddar cheese); set of measuring cups and spoon. Participants also received a SenseWear Pro energy expenditure device (BodyMedia).

What (procedures)? HPDH group consumed a diet consisting of 40:30:30. HPDH group to consume 15% of energy/d from dairy protein at 6–7 servings/d of dairy products. All dairy products needed to control dairy and calcium intakes were provided to participants in the HPDH groups and were generously donated by Agropur Dairy Cooperative. All participants were prescribed the same exercise regimen and underwent individual biweekly dietary counselling during the 16 wks. Individual diet counselling led by study dietitian and research nutrition. Participants engaged in various modes of aerobic exercise every day, 5 d/wk with us and 2 d on their own on the weekend. They were required to consume twice daily drinks (375 mL) of 1% artificially sweetened chocolate milk, directly after exercise and another at least 5 h before or after exercise.

Who provided? Diet: registered dietitians, research nutritionists. Exercise training: personal trainer, kinesiologist

How and where? Private nutrition counselling on a biweekly basis, location NR. Exercise in main fitness centre at McMaster University (exercise sessions were mainly individual or in small groups (i.e. 1 trainer to 2-3 participants).

When and how much? Diet: Biweekly session exercise training: supervised aerobic exercise 5 days per week and 2 days unsupervised exercise on the weekend. At each workout participants were to expend 250 kcal. Supervised progressive resistance training regimen 2 days per week (upper body, lower body split). Weight lifted by each participant recorded every session and increased once they could complete 3 sets of 10 repetitions or more at any given weight.

Strategies to improve or maintain fidelity; tailoring and modification: Every 2 wk thereafter, participants provided a 3-d food record to track compliance with the nutrition protocol. All 3-d food records were analysed with ESHA and participants were provided with feedback in their next biweekly private counselling session. During the week (Monday–Friday), they reported to our study office daily and were often given a SenseWear Pro energy expenditure device (BodyMedia) to wear, programmed for them, so they could track their energy expenditure during their workout. Compliance with weekend workouts was assessed by having women take home and wear the SenseWear Pro device on random occasions. Resistance exercise logs were completed by the trainer and aerobic exercise logs were completed by the participant and checked frequently by study personnel to ensure compliance.

Extent of intervention fidelity: HPDH group consumed -1.3 g/(kg × d) protein for 16 wks, which could have contributed to the lean mass gain in this group. In addition, the protein and carbohydrate intakes of the HPDH group (30 and 40% daily energy intake, respectively) were not as excessive as those employed in more extreme protocols. Dietary protein consumption increased in the HPDH group, and dietary calcium and vitamin D intake increased in the HPDH over 16 wks.

Concomitant interventions: NR

Control diet:

Josse 2011 (Continued)

Name (as reported) and brief description: Adequate-protein medium-dairy (APMD) diet. Consisting of 55% carbohydrates, 30% fat and 15% protein. Aerobic exercise 7 days a week to expend 250 kcal/day. Prescribed energy was maintenance energy requirements reduced by 500 kcal/d.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: Healthy premenopausal women with a mean (SE) age of 30 (5.5) years, with a mean (SE) BMI of 31.4 (3.3) kg/m², with a low dairy consumption (~< 500 mg/d Ca²⁺) and a sedentary lifestyle (exercise less than once/week)

Why? An adequate protein intake, along with medium dairy consumption, during a period of energy restriction, combined with daily exercise, may provide adequate levels of bone-supporting nutrients to positively affect markers of bone health.

What (materials)? Individualised plan outlining their required macronutrients intake in grams (corresponding to their new energy requirements); 2 study drinks/d (one immediately post-exercise and another drink at least 5 hours before or after exercise); Splenda-sweetened 1% chocolate milk). All dairy products required during the study period (1% artificially sweetened chocolate milk, white milk, yoghurt, cheddar cheese); set of measuring cups and spoon. Participants also received a SenseWear Pro energy expenditure device (BodyMedia).

What (procedures)? Participants completed a FFQ for calcium and dairy foods to verify low baseline consumption. Thereafter, they were instructed to complete a 7-day food record which provided a starting point on which dietary counselling was based. Maintenance energy requirements were calculated per participant, and reduced by 500 kcal/d in order to calculate each participant's targeted total energy intake throughout the study. Participants were provided with an individualised plan according to a high-protein, medium-dairy diet that included 3 to 4 servings of dairy products (of total energy: 55% carbohydrate; 30% fat and 15% protein, of which 7.5% from dairy protein). They were required to consume twice daily drinks (375 mL) of 1% chocolate milk, directly after exercise and another at least 5 h before or after exercise.

Who provided? Diet: registered dietitians, research nutritionists. Exercise training: personal trainer, kinesiologist

How and where? Private nutrition counselling on a biweekly basis, location NR. Exercise in main fitness centre at McMaster University (exercise sessions were mainly individual or in small groups (i.e. 1 trainer to 2-3 participants).

When and how much? Diet: Biweekly sessions exercise training: supervised aerobic exercise 5 days per week and 2 days unsupervised exercise on the weekend. At each workout participants were to expend 250 kcal. Supervised progressive resistance training regimen 2 days per week (upper body, lower body split). Weight lifted by each participant recorded every session and increased once they could complete 3 sets of 10 repetitions or more at any given weight

Strategies to improve or maintain fidelity; tailoring and modification: Every 2 wk thereafter, participants provided a 3-d food record to track compliance with the nutrition protocol. All 3-d food records were analysed with ESHA and participants were provided with feedback in their next biweekly private counseling session. Participants

Country and setting: Spain, outpatient university hospital in Reus

Eligibility criteria: Participants were aged between 30 and 60 years with BMI between 27 and 35 kg/m². Participants were excluded if they had uncontrolled type 2 diabetes (defined as HbA1c above 8%), systolic blood pressure or diastolic blood pressure above 159 or 99 mmHg, respectively, plasma LDL concentration above 160 mg/dL, plasma triglyceride concentration above 400 mg/dL; suspicion of secondary cause of obesity; presence of an inflammatory or chronic obstructive pulmonary disease, infection or active neoplasm; active endocrine or haematologic disease at the time of the study; blood leukocyte count $\geq 11 \times 10^6$ cells; were using anti-inflammatory drugs, steroids, hormones or antibiotics which could affect study outcomes; had changes in medication for lipids, diabetes or hypertension in the past three months; were alcoholic or drug-dependent (excluding tobacco); had a restrictive diet or more than 5 kg weight loss in the past three months; any medical condition which advised against inclusion; problems understanding the study, or reservations about adhering to the study diet.

Type 2 diabetes at baseline: No - confirmed by author: "T2D was not an exclusion criteria to participate in the study but, at the end, none of the participants had T2D".

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: Unclear

 Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-GI diet. Advised to consume 42% of energy from high-GI carbohydrates, 18% from protein and 40% from fat. GI = 62. Energy prescription was determined by subtracting 500 kcal/d from the total estimated baseline energy intake.

Treatment diet type (carbohydrate-fat-protein): Low-high-balanced

Exercise component? No

Juanola-Falgarona 2014 (Continued)

Recipients: Healthy adults (83% female, 17% male), with a mean age of 44.0 (8.2) years and a mean BMI of 30.8 (1.9) kg/m², with or without hypertension (5/40; 13%), hypercholesterlaemia (2/40; 5%)

Why? To determine whether an isocaloric diet, rich in high-glycaemic index carbohydrates has a smaller effect on weight loss, compared to a diet, rich in low-glycaemic index carbohydrates. "...low-carbohydrate diets were related to better improvements in the lipid profile. Nonetheless, in a pooled analysis that was based on observational studies, low-carbohydrate diets seemed to be associated with increased risk of all-cause mortality."

What (materials)? "...subjects received a dossier containing a leaflet with written general dietary recommendations, biweekly menus, and seasonal receipts. An informative website was available for all participants (<http://www.glyndiet.org/>)."

What (procedures)? "Participants were encouraged to eat whole grain cereals and pulses as the base of their diet, avoid the rice and potatoes, and were also recommended to select specific types of fruit (apple, orange, peach) and vegetables (courgette, tomato, onion) with low GI, avoiding the ripe pieces. They were advised to reduce the time cooking of carbohydrate rich-foods in order to maintain the low GI of the foods. The principal animal protein sources of the diet were white fish and white meat. In order to obtain the desired weight loss, a 500 kcal restriction in diet was applied to each participant. Total daily energy expenditure for each participant was estimated using the WHO (2001) equations corrected by the physical activity degree. Diets were designed at 1500, 1700, 2000, and 2500 kcal/d, and all participants were categorised as having one of the 4 categories of dietary energy content after subtracting 500 kcal/d of the total estimated energy intake to achieve a desired weight loss."

Who provided? Dietitian

How and where? Face-to-face personalised advice was given to each patient.

When and how much? Individual examination visits at baseline, after 2 weeks and thereafter monthly. Unclear at which of these visits the intervention was reinforced. The study authors reported: "Across the visits, different evaluations and questionnaires were conducted to assess changes on anthropometry and the adherence to the intervention".

Strategies to improve or maintain fidelity; tailoring and modification: "Dietary intake was estimated at baseline and at the 1st, 3th and 6th month of intervention by mean of 3-day dietary records including two workdays and a weekend day. Subjects were encouraged to weigh the food that they eat; otherwise trained dietitians estimated weight using an illustrated book of food portions. Energy and nutrient intake were calculated from Spanish food composition tables. Values of GI for each food were extracted from the International Glycemic Index and Glycemic Load Values using glucose as the reference scale."

Extent of intervention fidelity: NR

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Low-fat diet. Advised to consume 52% of energy from high-GI carbohydrates, 18% from protein and 30% from fat. GI = 65. Energy prescription was determined by subtracting 500 kcal/d from the total estimated baseline energy intake.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Healthy adults (78% female, 22% male), with a mean age of 44.1 (8.2) years and a mean BMI of 30.8 (1.9) kg/m², with or without hypertension (5/40; 13%), hypercholesterlaemia (5/40; 13%)

Why? To determine whether an isocaloric low-fat diet, rich in high-glycaemic index carbohydrates, has a smaller effect on weight loss, compared to a diet, rich in low-glycaemic index carbohydrates

What (materials)? "...subjects received a dossier containing a leaflet with written general dietary recommendations, biweekly menus, and seasonal receipts. An informative website was available for all participants (<http://www.glyndiet.org/>)."

Juanola-Falgarona 2014 (Continued)

What (procedures)? Subjects randomised to a low-fat diet were also advised to maintain a high-GI diet but with lower fat content. Participants had to follow a low-fat diet fulfilling the criteria defined by the American Heart Association (30% of energy from fat, 52% of energy from high-glycaemic index carbohydrates, 18% of energy from proteins). Participants were encouraged to eat refined grain cereals, fruits (banana, kiwi, melon) and vegetables (carrot, green bean, cabbage) with high GI, and avoid pulses. Additionally, daily sugar was substituted by glucose in order to rise GI of this intervention. In this case, they were recommended to avoid red meat and blue fish due its high fat content and also recommended to eat low-fat dairy products. In order to obtain the desired weight loss, a 500 kcal restriction in diet was applied to each participant. Total daily energy expenditure for each participant was estimated using the WHO (2001) equations corrected by the physical activity degree.

Who provided? Dietitian

How and where? Face-to-face personalised advice was given to each patient.

When and how much? Individual examination visits at baseline, after 2 weeks and thereafter monthly. Unclear at which of these visits the intervention was reinforced. The study authors reported: " Across the visits, different evaluations and questionnaires were conducted to assess changes on anthropometry and the adherence to the intervention".

Strategies to improve or maintain fidelity; tailoring and modification: "Dietary intake was estimated at baseline and at the 1st, 3th and 6th month of intervention by mean of 3-day dietary records including two workdays and a weekend day. Subjects were encouraged to weigh the food that they eat; otherwise trained dietitians estimated weight using an illustrated book of food portions. Energy and nutrient intake were calculated from Spanish food composition tables. Values of GI for each food were extracted from the International Glycemic Index and Glycemic Load Values using glucose as the reference scale."

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low carbohydrate (LC) diet. Approximately 33% energy as carbohydrate, 27% as fat and 40% as protein (7% saturated fat, 6% PUFA and 13% MUFA) with 26 g fibre. Energy prescription of ~ 6000 kJ per day

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: N = 13 (gender NR) with mean (SE) age 50.1 (1.4) years, mean (SE) BMI 32.6 (1.0) kg/m², mean (SE) weight 91.5 (4.1) kg

Why? "Weight loss per se is usually associated with reductions in LDL-C and reducing saturated fat also decreases LDL-C. We therefore developed a diet low in saturated fat and low in carbohydrate to maximise LDL-C reduction and reduce glucose concentrations designed to achieve moderate weight loss in order to test whether the combined effects with weight loss would improve FMD."

What (materials)? NR

What (procedures)? Participants were prescribed a weight-loss diet that was low carbohydrate: 33% energy as carbohydrate, 27% energy as fat, 40% energy as protein, 7% energy from saturated fat, 6% energy from PUFA and 13% energy from MUFA and 26 g fibre. Both diets were designed to be 6000 kJ so that weight loss would approximate 0.5–1 kg per week. Subjects saw the dietitian individually at the start of weight loss and every 2 weeks and also attended monthly group meetings for follow-up consultations.

Who provided? Dietitian

How and where? Face-to-face at the Commonwealth Scientific Industrial Research Organisation clinic

When and how much? Every two weeks during the weight loss phase and monthly during the follow-up phase

Strategies to improve or maintain fidelity; tailoring and modification: "Records of daily food intake were maintained in order to monitor food intake. The dietary data were analysed using FoodWorks version 3.1 dietary analysis software (Xyris Software, Highgate Hill, Australia). In order to ensure that the energy restriction was approximately 30% below estimated usual intake a FFQ was completed at baseline to assess usual energy and nutrient intake."

Extent of intervention fidelity: NR

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: High-carbohydrate (HC) diet. Approximately 20% energy as fat, 20% as protein and 60% from carbohydrate (4% saturated fat, 5% PUFA and 7% MUFA) with 40 g fibre. Energy prescription of ~6000 kJ per day

Keogh 2007 (Continued)

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 12 (gender NR) with mean (SE) age 469 (1.6) years, mean (SE) BMI 33.2 (0.8) kg/m², mean (SE) weight 97.6 (2.4) kg

Why? NR

What (materials)? NR

What (procedures)? Participants were prescribed a high-carbohydrate, low-fat (20% energy as fat, 20% energy as protein and 60% energy as carbohydrate, 4% energy from saturated fat, 5% from PUFA and 7% from MUFA and 40 g fibre). Both diets were designed to be 6000 kJ so that weight loss would approximate 0.5–1 kg per week. Subjects saw the dietitian individually at the start of weight loss and every 2 weeks and also attended monthly group meetings for follow-up consultations.

Other notes about methods: ITT approach was not used.

Participants

Country and setting: USA, outpatient clinical research centre at a university in Knoxville. All food required to complete the respective diets were provided, predominantly as frozen foods.

Eligibility criteria: Premenopausal women aged 20–50 years with a BMI > 30 to < 55 kg/m². fasting glucose < 110 mg/dL and 2-h glucose level < 170 mg/dL. Participants were excluded if they had proteinuria or elevated serum creatinine (> 1.5 mg/dL), surgical or premature menopause, history of liver disease or abnormal liver function tests, diabetes, thyroid disease with abnormal thyrotropin, weight > 350 lbs, triglycerides > 400 mg/dL or LDL cholesterol > 160 mg/dL, systolic blood pressure > 145 mmHg or diastolic blood pressure > 100 mmHg, used medications known to affect lipid or glucose metabolism (niacin, steroids, and statins), were pregnant or wanted to become pregnant in the next six months, had weight loss of > 5% of body weight in the last six months, or had a history of cancer undergoing active treatment.

Type 2 diabetes at baseline: No

Impaired glucose tolerance at baseline: Unclear

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein low-carbohydrate (HP) diet, 40% carbohydrates, 30% fat and 30% protein. Energy prescription 500 kcal/day from calculated maintenance needs established by resting energy expenditure

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: N = 12 women with a mean (SE) age of 35.9 (2.1) years and mean (SE) BMI of 41.3 (1.8) kg/m² with no history of diabetes or prediabetes

Why? A hypocaloric high-protein diet may result in the suppression of hunger and induction of satiety, resulting in weight loss. It may also result in a positive nitrogen balance, therefore assisting in the maintenance of lean body mass, compared to a hypocaloric high-carbohydrate diet. Furthermore, it may have positive effects on metabolic parameters, such as b-cell function, cardiovascular risk factors, oxidative stress, and lipid peroxidation.

What (materials)? At baseline, an individualised weekly food diary (which included the participant's preferences) was printed and given to each subject with instructions for recording all food intake on a daily basis. Weekly provision of fresh, prepackaged, and frozen foods for the duration of the study. Most of the entrees for the diet were frozen entrees purchased directly from the manufacturer. The diet included 1 cup of frozen vegetables at both lunch and dinner. Snacks in between meals included shakes and meal bars. Participants were given all food needed to meet their dietary assignment for the duration of the study. All food was dispensed by the dietitian at the CRC on a weekly basis to each participant. An individualised weekly food diary (which included the participant's preferences) was printed and given to each subject with instructions for recording all food intake on a daily basis.

What (procedures)? High-protein (40% carbohydrates, 30% fat, and 30% protein) hypocaloric diet for 6 months. Weight reduction caloric needs were established for each individual by subtracting 500 kcal/day from their calculated maintenance needs established by REE. Weight loss of 1–2 lbs weekly was targeted. On average, an 1800 kcal/day diet for a 70-kg individual was used to achieve adequate weight loss. If a subject reached a plateau and did not lose weight for two consecutive weeks, calories were reduced by an additional 200 kcal or to a minimum of 1200 kcal/day. Caloric adjustments were made by altering the amount of supplement bars and/or shakes. Since these were very similar to the nutrient composition of each diet, they could be easily taken out of the diet to reduce calories but maintain adequate nutrient composition. The study diets provided more than the recommended amount of calcium (1000 mg/day) for women 20–50 years of age by providing an average of 1725 mg for HC and 1684 mg for HP diets. Both HP and HC diets were designed to minimise participant health risks. Dietary fat sources focussed on monounsaturated and polyunsaturated fats, i.e. plant oils, semi-liquid margarine, and nuts; dietary carbohydrate sources emphasised whole grains, fruits, vegetables, and legumes;

Kitabchi 2013 (Continued)

and dietary protein sources included lean meats, fish, chicken, eggs, and nonfat dairy foods, i.e. fat-free milk and low-fat cheese, consistent with American Diabetes Association and Institute of Medicine guidelines.

Who provided? Dietitian

How and where? "All participants were seen in the Clinical Research Center (CRC) at the University of Tennessee Health Science Center for all their visits."

When and how much? Every week for 24 weeks. If a participant did not lose weight for two consecutive weeks, calories were reduced by an additional 200 kcal or to a minimum of 1200 kcal/day altering the amount of supplement bars and/or shakes provided.

Strategies to improve or maintain fidelity; tailoring and modification: Subjects were asked to turn in completed food diaries each week in order to pick up the next week's food. At times, the dietitian adjusted the participant's meal choices if issues arose regarding compliance. Studies have shown increased dietary compliance with frequent interaction, an individualised diet with food variety, and some form of food recording system. The study dietitian assessed compliance by both subjective and objective parameters including weekly individual contact with patients that included a detailed review of their food diaries.

Extent of intervention fidelity: Compliance mean (SE) 94 (1.5)%

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: High-carbohydrate low-protein (HC) diet, 55% carbohydrates, 30% fat and 15% protein. Energy prescription 500 kcal/day from calculated maintenance needs established by resting energy expenditure

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 12 women with a mean (SE) age of 35.4 (2.0) years and mean (SE) BMI of 37.0 (1.5) kg/m² with no history of diabetes or prediabetes

Why? A hypocaloric high-protein diet may result in the suppression of hunger and induction of satiety, resulting in weight loss. It may also result in a positive nitrogen balance, therefore assisting in the maintenance of lean body mass, compared to a hypocaloric high-carbohydrate diet. Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-glycaemic load (LGL) diet, aimed to achieve intake of 35 to 40% of energy from fat, 25 to 30% from protein and 30 to 35% from carbohydrates and up to 3% from alcohol. A 500 kcal/d deficit relative to the estimated daily energy requirements was recommended.

Treatment diet type (carbohydrate-fat-protein): Low-high-high

Exercise component? No

Recipients: Participants with varying degrees of the metabolic syndrome (mean 2.8) , 54% female, aged 50.1 (9.3) with weight 100.0 (16.4) kg.

Why? Recent evidence shows that low-carbohydrate diets are as effective as low-fat diets in reducing body weight for up to one year, with some variation in the effect on lipids. Low-carbohydrate diets are an alternative which are still being assessed for long-term safety.

What (materials)? Dietary suggestions and recipes were made available.

What (procedures)? After a 48-hour dietary recall at screening, subjects were instructed to follow a low-glycaemic load diet and asked to fill each plate of food with one-third protein. For two meals per day the remaining two-thirds were vegetables, salads and legumes; for the third meal the balance of the plate was made up of low-glycaemic index bread and other carbohydrates. Individual and group dietary counselling sessions were offered over the course of the study, as well as a seven-day dietary recall during the intervention period.

Who provided? A dietitian provided individual and group counselling sessions.

How and where? Face-to-face counselling sessions with dietitian, in individual as well as group format. Location of sessions NR

When and how much? Individual counselling sessions with the dietitian occurred at baseline, week 2, month 1 and month 9. Group sessions led by the dietitians occurred at months 2, 3, 4, 5 and 6. Duration of sessions NR

Strategies to improve or maintain fidelity; tailoring and modification: After the first month, sessions were held in groups until month 6; seven-day dietary recall at month 3, regular weigh-in as part of study outcomes. A 48-h dietary recall was obtained at the screening visit to help the dietitian evaluate the diet prior to intervention. A 7-day dietary questionnaire was obtained at 3 months.

Extent of intervention fidelity: NR

Concomitant interventions: antihypertensives

Control diet:

Name (as reported) and brief description: Low-fat diet, aimed to achieve intake of < 30% energy from fat, about 15% from protein and 55 to 60% from carbohydrates and up to 3% from alcohol. A 500 kcal/d deficit relative to the estimated daily energy requirements was recommended.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Klemsdal 2010 (Continued)

Recipients: Participants with varying degrees of the metabolic syndrome (mean 2.9), 62% female, aged 49.9 (8.4) with weight 99.9 (14.7) kg

Why? Epidemiological studies report mixed findings on the role of total carbohydrate intake, as well as proportion of high-glycaemic index carbohydrates, as a cause of obesity and diabetes, therefore the European Society of Cardiology and American Heart Association have not thus far recommended reducing total carbohydrates or using glycaemic index to guide diets.

What (materials)? Dietary recommendations were based on the 2004 Nordic guidelines (Becker 2005) as well as the 2007 lifestyle recommendations of the European Society of Cardiology (Graham 2007).

What (procedures)? After a 48-hour dietary recall at screening, subjects were asked to follow a low-fat diet with a focus on unrefined, high-fibre carbohydrates; subjects were not instructed to consume low-glycaemic index carbohydrates. Individual and group dietary counselling sessions were offered over the course of the study, as well as a seven-day dietary recall during the intervention period.

Who provided? A dietitian provided individual and group counselling sessions.

How and where? Face-to-face counselling sessions with dietitian, in individual as well as group format. Location of sessions NR

When and how much? Individual counselling sessions with the dietitian occurred at baseline, week 2, month 1 and month 9. Group sessions led by the dietitians occurred at months 2, 3, 4, 5 and 6. Duration of sessions NR

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-fat high-protein diet. Prescribed 30% of energy as protein, 40% as carbohydrate and 30% as fat. Energy prescription to reduce total energy intake by 2000 kJ/day using an individualised dietary prescription based on estimation of energy requirements

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: Subjects were 54% female, aged mean (SD) 57.7 (9.9), BMI mean (SD) 36.6 (6.7). 61.8% on lipid-lowering drugs, 77.3% on BP-lowering drugs and years on average with the diagnosis of diabetes of over 7 years.

Why? Substituting protein for carbohydrate while maintaining reduced total fat may have particular benefits in type 2 diabetes. High-protein diets promote weight loss, maintain lean body mass and improve lipid and glycaemic profiles in obese non-diabetic individuals. Studies specifically in type 2 diabetes are limited, are generally short, often using very intensive interventions and/or providing a significant proportion of participants' food, making the translation of the findings to a general population difficult. Therefore the specific long-term effect of increasing protein intake in individuals with type 2 diabetes in a free-living situation, using an intervention that can be realistically implemented, requires further investigation.

What (materials)? Portion charts, sample diet plans and culturally appropriate recipes were made available for specific ethnic groups.

What (procedures)? low-fat high-protein (30% of energy as protein, 40% as carbohydrate, 30% as fat). Group sessions every 2 weeks with an education component and time for discussing and concluded with goal-setting. Dietary counselling included information on appropriate intakes and physical activity advice.

Who provided? Dietitian

How and where? Face-to-face, individual and group sessions

When and how much? At the beginning of the study, individualised dietary prescription based on estimation of energy requirements were discussed on a one-to-one basis with each participant. Participants mainly had group sessions thereafter which were 1 hour long consisting of diet-specific information and education and were conducted every 2 weeks for the first 6 months, then every month for the second 6 months. No further dietary advice was offered by the dietitians after 12 months. Participants were then asked to continue following their prescribed diets on their own in the second year. Outcome measures were assessed at 6, 12 and 24 months.

Strategies to improve or maintain fidelity; tailoring and modification: The programmes were specifically designed for delivery in a 'real-world' setting, keeping the time commitment for both participants and staff to levels that could be readily achieved in most healthcare systems. Ongoing self-

Krebs 2012 (Continued)

recording of food intake. Weekly text or email reminders and motivational messages were also offered to participants to enhance adherence to the diets.

Extent of intervention fidelity: NR

Concomitant interventions: Hypoglycemics, lipid-lowering and antihypertensives

Control diet:

Name (as reported) and brief description: Low-fat high-carbohydrate diet. Prescribed 15% of energy as protein, 55% as carbohydrate and 30% as fat. Energy prescription to reduce total energy intake by 2000 kJ/day using an individualised dietary prescription based on estimation of energy requirements

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Subjects were 66% female, aged mean (SD) 58.0 (9.2), BMI mean (SD) 36.7 (6.4). 69.3% on lipid-lowering drugs, 74.5% on BP-lowering drugs and on average with the diagnosis of diabetes of over 7 years.

Why? NR

What (materials)? Portion charts, sample diet plans and culturally appropriate recipes were made available for specific ethnic groups.

What (procedures)? a low-fat high-carbohydrate (15% of energy as protein, 55% as carbohydrate, 30% as fat) diet. Group sessions every 2 weeks with an education component and time for discussing and concluded with goal-setting. Dietary counselling included information on appropriate intakes and physical activity advice.

Who provided? Dietitians

How and where? Face-to-face, individual and group sessions

When and how much? At the beginning of the study, individualised dietary prescription based on estimation of energy requirements were discussed on a one-to-one basis with each participant. Participants mainly had group sessions thereafter which were 1 hour long consisting of diet-specific information and education and were conducted every 2 weeks for the first 6 months, then every month for the second 6 months. No further dietary advice was offered by the dietitians after 12 months. Participants were then asked to continue following their prescribed diets on their own in the second year. Outcome measures were assessed at 6, 12 and 24 months.

Strategies to improve or maintain fidelity; tailoring and modification: The programmes were specifically designed for delivery in a 'real-world' setting, keeping the time commitment for both participants and staff to levels that could be readily achieved in most healthcare systems. Ongoing self-recording of food intake. Weekly text or email reminders and motivational messages were also offered to participants to enhance adherence to the diets.

Extent of intervention fidelity: NR

Concomitant interventions: Hypoglycemics, lipid-lowering and antihypertensives

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: No

Change in BMI (kg/m²) at ≥ 12 months: No

Krebs 2012 (Continued)

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: Yes

Change in SBP (mmHg) at ≥ 12 months: Yes

All-cause mortality at ≥ 12 months: No

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥ 12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: Yes

Change in LDL (mmol/L) at ≥ 12 months: Yes

Change in HDL (mmol/L) at ≥ 12 months: Yes

Change in non-HDL (mmol/L) at ≥ 12 months: No

Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: Yes

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: Yes

Participant-reported adverse effects: No

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate high-protein (LCHP) ad libitum diet; participants were instructed to maintain carbohydrate intake of less than 30 g/day and dietitian calculated the minimum grams of high biological value (HBV) protein to be eaten daily.

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? No

Recipients: Healthy adults aged 18 to 55 years, with a BMI > 27 kg/m²

Why? To determine changes in lean body mass and fat mass using a DEXA scan on ketogenic diets

What (materials)? Diet materials (not specified), sample menus and carbohydrate counting booklets

What (procedures)? Based on the measurement of lean body mass (DEXA), the minimum daily amount of high biological value protein (HBV) was calculated. Participants were instructed on HBV sources. A carbohydrate counter booklet assisted them in maintaining their carbohydrate intake at < 30 grams per day. They were encouraged to use salt and Morton Lite Salt ad libitum to supplement diuretic losses of sodium and potassium. Participants were instructed to continue their current physical activity, to drink at 64 oz of non-caffeinated calorie-free fluid per day and take a multiple vitamin and mineral supplement. No specific exercise routine was recommended.

Who provided? Dietitian

How and where? Individualised face-to-face counselling at the clinic

When and how much? Weekly (12 visits). At each follow-up visit the diet was reinforced.

Landers 2002 (Continued)

Strategies to improve or maintain fidelity; tailoring and modification: Participants recorded their food intake in a diary; this diary was reviewed weekly. They were weighed and also provided a weekly urine specimen to check for ketones.

Extent of intervention fidelity: The extent of dietary non-compliance was NR for this intervention group. However, the study authors reported the following: " ... it was evident that some subjects were non-compliant to the diet." ; "LCHP dieters did not consistently spill ketones in the urine"; "There were subjects on LCHP diets who continued to eat beans, cornbread, and other starchy foods on a regular basis despite weekly education".

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Conventional diet; macronutrient distribution of 50% carbohydrate, 20% protein and 30% fat. Energy prescription was based on adjusted body weight and the Harris-Benedict equation to estimate energy needed to promote 0.45 kg weight loss per week.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Healthy adults aged 18 to 55 years, with a BMI > 27 kg/m²

Why? To provide data on body composition changes on a conventional weight loss diet, such as the amount of lean and fat mass) during periods of weight loss

What (materials)? Diet plans were based on the diabetic exchange lists and each subject received a customised sample meal plan as well as a copy of Exchange lists for meal planning. A food diary was also provided.

What (procedures)? Using adjusted body weight (actual weight - ideal weight) * 0.25 + ideal body weight) and the Harris Benedict equation estimated energy needed to promote weight loss of 0.45kg. No subject was given a diet less than 1200 kCal. All subjects were instructed to continue their physical activity, drink at least 64 oz of non-caffeinated calorie-free fluid per day, take a multiple mineral and vitamin supplements.

Who provided? Dietitian

How and where? Individualised face-to-face counselling at the clinic

When and how much? Weekly (12 visits). At each follow-up visit the diet was reinforced.

Strategies to improve or maintain fidelity; tailoring and modification: Participants recorded their food intake in a diary; this diary was reviewed weekly. They were also weighed.

Extent of intervention fidelity: The extent of dietary non-compliance was NR for this intervention group.

Concomitant interventions: NR

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Baseline characteristics were reported for ITT population.

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:
Name (as reported) and brief description: High-protein (HP) diet consisting of 30% of energy from protein (lean meat, chicken and fish), 40% from carbohydrate and 30% from fat (7% saturated, 10% PUFA and 13% MUFA). Energy prescription of ~6400 kJ/day or 30% energy restriction for three months, followed by energy balance for nine months

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: Participants were n = 30 (57%) male with a mean (95% CI) age of 59.6 (57.5, 61.8) years, mean (95% CI) duration of DM 8.7 (6.8, 10.5) years, mean (95% CI) weight 94.6 (90.5, 98.8) kg, mean (95% CI) HbA1C 7.89 (7.63, 8.15) %, mean (95% CI) total cholesterol 4.73 (4.50, 4.96) mmol/L, mean (95% CI) LDL 2.49 (2.28, 2.70) mmol/L, mean (95% CI) HDL 1.19 (1.11, 1.24) mmol/L, mean (95% CI) triglycerides 2.39 (2.01, 2.76) mmol/L, mean (95% CI) systolic BP 131.8 (128.8, 134.8) mmHg, mean (95% CI) diastolic BP 81.5 (79.5, 83.6) mmHg.

Why? A high-protein low-carbohydrate diet may improve glycaemic control and insulin sensitivity in people with type 2 diabetes mellitus; however the long term health effects of such a diet is poorly understood.

What (materials)? "written materials were supplied to both groups containing information on the key nutrition intervention messages, prescriptive fixed menu plans and food choice lists."

What (procedures)? Dietary intakes of each participant were calculated from weighed/measured food records collected at baseline (5 days). Diet-specific advice was administered to each study participant. The diet consisted of 30% energy intake from protein (a combination of lean meat, chicken and fish) and 40% energy intake from carbohydrate; low-glycaemic index carbohydrates were recommended.

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

193

Larsen 2011 (Continued)

The diet provided 30% of total energy from fat (7% saturated fat, 10% polyunsaturated fat, 13% monounsaturated fat). The dietary intervention consisted of an initial 3-month energy restriction (6400 kJ/day or 30% energy restriction), followed by 9 months of energy balance. Topics at group meetings included healthy cooking, goal-setting and problem-solving, physical activity, and supportive counselling. Physical activity was encouraged as a strategy to increase energy expenditure for those without limitations or complications, and the recommendations were consistent with public health guidelines.

Who provided? Dietitian

How and where? Face-to-face dietary counselling appointments conducted at the Baker IDI Heart and Diabetes Institute (Melbourne, Australia)

When and how much? Individual sessions; four visits during the 3-month energy restrictive period (total of 2.5 hours), and five visits during the 9 months of energy balance (total of 2.5 hours). Group meetings: every 3 months (total of 3.3 hours)

Strategies to improve or maintain fidelity; tailoring and modification: "Dietary intakes were calculated from weighed/measured food records collected at baseline (5 days) and every 3 months during the intervention period (1 day/month) using Australia-specific dietary analysis software (Foodworks; Xyris Software, Highgate Hill, QLD, Australia). Dietary compliance was monitored by self-reported food intakes and 24-h urine samples for an assessment of urea excretion as a marker of protein intake." Self-reported physical activity was measured using the validated Active Australia survey questionnaire.

Extent of intervention fidelity: Attendance at individual sessions: 25% of participants attended 9 individual sessions; while 21% missed one session. Attendance at group sessions: ranged from 26% to 37% per session. Ability to self-manage the diet (score): median 4 (IQR 3 to 4). Urinary nitrogen excretion: study authors reported higher levels at 3 months, and at 12 months; however they stated the following at 12 months: "significance was lost following conservative statistical correction".

Concomitant interventions: Insulin, n (%): 10/53 (19); oral glycaemic tablets, n (%): 38/53 (72)

Control diet:

Name (as reported) and brief description: High-carbohydrate (HC) diet consisting of 15% of energy from protein, 55% from carbohydrate and 30% from fat (7% saturated, 10% PUFA and 13% MUFA). Energy prescription of ~6400 kJ/day or 30% energy restriction for three months, followed by energy balance for nine months

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: Participants were n = 18 (39) male with a mean (95% CI) age of 58.8 (55.8, 61.7) years, mean (95% CI) duration of DM 8.6 (6.6, 10.6) years, mean (95% CI) weight 95.5 (91.5, 99.6) kg, mean (95% CI) HbA1C 7.78 (7.50, 8.05) %, mean (95% CI) total cholesterol 4.71 (4.40, 5.01) mmol/L, mean (95% CI) LDL 2.42 (2.16, 2.68) mmol/L, mean (95% CI) HDL 1.20 (1.12, 1.28) mmol/L, mean (95% CI) triglycerides 2.37 (1.85, 2.90) mmol/L, mean (95% CI) systolic BP 127.4 (124.5, 130.2) mmHg, mean (95% CI) diastolic BP 81.5 (78.8, 84.2) mmHg.

Why? Consensus-based nutritional guidelines currently recommend diets that are high in carbohydrates (45–65% of total daily energy intake) and low in fat (< 30% of energy intake) for people with Type 2 diabetes mellitus.

What (materials)? Written materials containing information on key nutrition intervention messages, prescriptive fixed menu plans and food choice lists

What (procedures)? Dietary intakes of each participant were calculated from weighed/measured food records collected at baseline (5 days). Diet-specific advice was administered to each study participant. The diet consisted of 15% energy intake from protein (a combination of lean meat, chicken and fish) and 55% energy intake from carbohydrate; low-glycaemic index carbohydrates were recommended. The diet provided 30% of total energy from fat (7% saturated fat, 10% polyunsaturated fat, 13% monounsaturated fat). The dietary intervention consisted of an initial 3-month energy restriction (6400 kJ/day or 30% energy restriction), followed by 9 months of energy balance. Topics at group meetings included healthy cooking, goal-setting and problem-solving, physical activity, and supportive coun-

Group differences at baseline: Yes

Characteristic(s) with significant group difference and relevant statistic: characteristic 1: insulin (P < 0.05); intervention vs control

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: PRO diet. Prescribed dietary protein at 1.6 g/kg/d (~30% of energy intake) and carbohydrate < 170 g/d (~40% of energy) and dietary lipids ~30% energy intake. Recommendation for 30 min of walking 5 d/week. Energy prescription of 7100 kJ/d

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: N = 25 (gender NR) with mean (SEM) weight 96.6 (3.9) kg, mean (SEM) BMI 33.8 (1.1) kg/m², mean (SEM) total cholesterol 5.33 (0.19) mmol/L, mean (SEM) LDL 3.41 (0.16), mean (SEM) HDL 1.14 (0.07) mmol/L, mean (SEM) triglycerides 1.72 (0.18) mmol/L

Why? "Reducing carbohydrate intake with replacement of either fat or protein has been shown to reduce TAG and increase HDL-C even under weight stable conditions. Substitution with protein may be more beneficial than fat for lipid changes and improvement in INS action. Indeed, independent effects of protein on glycemic regulation suggests protein may be a more effective dietary change than increases in fat intake for reducing risk for metabolic disease."

What (materials)? "Each group received a menu plan with meals for each day meeting established nutritional requirements and dietary lipid guidelines. Subjects were provided electronic food scales and instructed to weigh foods at all meals." Armband accelerometers also provided

What (procedures)? The prescribed PRO diet provided dietary protein at 1.6 g/kg-1/d-1 and < 170 g/d carbohydrate (~30% and ~40% of energy intake, respectively). Dietary lipids were constant between diets (~30% energy intake). For the PRO group, education guidelines emphasised use of high-quality proteins including lean meats, dairy and eggs. Both diets included 5 servings/d of vegetables and 2 to 3 servings/d of fruit. After baseline data collection, subjects received instructions from a research dietitian about their specific diet including menus, food substitutions, portion sizes, and procedures for maintaining weighed diet records. Activity guidelines emphasised lifestyle recommendations for physical activity based on NIH Guidelines for Weight Management. These guidelines recommend a minimum of 30 min of walking 5 d/wk. Participation in physical activity for the groups was voluntary. Physical activity was monitored using daily activity logs and 3 d/mo subjects wore armband accelerometers (BodyMedia, Cincinnati, OH). Activity logs were collected each week. Subjects also attended 1-hour meetings for 4 months.

Who provided? Dietitian

How and where? Face-to-face at the nutrition research facility

When and how much? Diet intervention lasted for 4 months. At baseline instructions on diet including menus, food substitutions, portion sizes, and procedures for maintaining weight records. Over 4 months, weekly 1-hr group meetings with dietitian who provided diet and exercise information and reviewed diet records for treatment compliance. Weekly weight checks were done. Physical activity was monitored using daily activity logs and armband accelerometers. At the end of 4 months blood tests were conducted fasting and 1- and 2-hr post-prandial as a meal challenge.

Strategies to improve or maintain fidelity; tailoring and modification: "Nutrient intakes were evaluated as mean daily intakes from 3-d weighed records using Nutritionist Pro software (First DataBank Inc. 2003, San Bruno, CA) to improve compliance."

Extent of intervention fidelity: NR

Lasker 2008 (Continued)

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: CHO diet. Provided dietary protein equal to 0.8 g/kg/d (~15% of energy intake) and carbohydrate 220 g/d (~55% of energy) and total fat ~30% of energy intake. Recommendation for 30 min of walking 5 d/week. Energy prescription of 7100 kJ/d

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: N = 25 (gender NR) with mean (SEM) weight 94.3 (2.1) kg, mean (SEM) BMI 33.4 (0.7) kg/m², mean (SEM) total cholesterol 5.52 (0.17) mmol/L, mean (SEM) LDL 3.49 (0.13), mean (SEM) HDL 1.27 (0.07) mmol/L, mean (SEM) triglycerides 1.66 (0.17) mmol/L

Why? To assess whether conventionally accepted carbohydrate is better than moderate-carbohydrate diet at achieving greater fat mass loss and more favourable changes in post-prandial insulin response and features of dyslipidaemia

What (materials)? "Each group received a menu plan with meals for each day meeting established nutritional requirements and dietary lipid guidelines. Subjects were provided electronic food scales and instructed to weigh foods at all meals." Armband accelerometers also provided

What (procedures)? The prescribed CHO diet provided dietary protein at 0.8 g/kg-1/d-1 and > 220 g/d carbohydrate (~15% and ~55% of energy intake respectively). Education guidelines for the CHO group followed USDA MyPyramid and emphasised restricting dietary fat and cholesterol with use of whole grain breads, rice, cereals and pasta. Both diets included 5 servings/d of vegetables and 2 to 3 servings/d of fruit. After baseline data collection, subjects received instructions from a research dietitian about their specific diet including menus, food substitutions, portion sizes, and procedures for maintaining weighed diet records. Activity guidelines emphasised lifestyle recommendations for physical activity based on NIH Guidelines for Weight Management. These guidelines recommend a minimum of 30 min of walking 5 d/wk. Participation in physical activity for the groups was voluntary. Physical activity was monitored using daily activity logs and 3 d/mo subjects wore armband accelerometers (Body-Media, Cincinnati, OH). Activity logs were collected each week.

TG (mmol/L): mean (SD) 1.4 (0.48)

Group differences at baseline: Yes

Characteristic(s) with significant group difference and relevant statistic: characteristic 1: BMI (P = 0.047); NR between which arms

Other notes about participants: Four trial arms in the study. There were group differences, but these were between the 4 groups.

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: The PRO diet provided 1.6 g/kg.day protein (~30%), ~30% fat and ~40% carbohydrates. Energy prescription of 7100 kJ/d.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: Women only N = 12 with mean (SE) age 47.0 (1.7) years, mean (SE) weight 91.1 (5.1) kg, mean (SE) BMI 34.8 (1.8) kg/m²

Why? NR

What (materials)? "We developed a 2-wk menu plan for each group with meals for each day meeting established nutritional requirements and lipid guidelines." Participants also received food scales.

What (procedures)? The PRO diet provided dietary protein at 1.6 g/kg/d (30% of energy intake) with a carbohydrate:protein ratio > 1.5 and dietary lipids at roughly 30% energy intake. These diets were designed to fall within the Acceptable Macronutrient Distribution Range established by the Institute of Medicine with minimum Recommended Dietary Allowance (RDA) intakes for carbohydrates = 130 g/d and protein = 0.8 g/kg and with upper limits for carbohydrates < 65% and protein < 35% of total energy intake. The 2 diets were formulated to be equal in energy (7100 kJ/d; 1700 kcal/d), total fat intake (57 g/d) and fibre (17 g/d). For the PRO group, the education guidelines emphasised use of high-quality proteins including meats, dairy, and eggs. Both diets included 5 servings/d of vegetables and 2–3 servings of fruits.

Layman 2005 (Continued)

Who provided? Dietitian

How and where? Face-to-face group sessions at the weight management research facility

When and how much? During the 16-wk weight loss programme, subjects were required to attend a 1-h meeting each week at the weight management research facility.

Strategies to improve or maintain fidelity; tailoring and modification: Reductions in energy intake determined from weekly 3-d weighed food records.

Extent of intervention fidelity: Subjects in the PRO groups maintained protein intakes of 107 g/d and 30% of energy intake. The ratio of carbohydrate:protein was 1.24. Total dietary lipid intake decreased to 49 g/d (32% of dietary energy) and SFA decreased to 19.1 g/d (12.4% of energy).

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: The CHO diet provided 0.8 g/kg.day protein (~15%), ~30% fat and ~55% carbohydrates. Energy prescription of 7100 kJ/d

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Women only N = 12 with mean age (SE) 45.2 (1.4) years, mean (SE) weight 93.7 (3.5) kg, mean (SE) BMI 35.4 (1.1) kg/m²

Why? NR

What (materials)? "We developed a 2-wk menu plan for each group with meals for each day meeting established nutritional requirements and lipid guidelines." Participants also received electronic food scales.

What (procedures)? The CHO diet provided dietary protein at 0.8g/kg/d (15% of energy intake) with a carbohydrate:protein ratio > 3.5 and dietary lipids at roughly 30% energy intake. These diets were designed to fall within the Acceptable Macronutrient Distribution Range established by the Institute of Medicine with minimum Recommended Dietary Allowance (RDA) intakes for carbohydrates = 130 g/d and protein = 0.8 g/kg and with upper limits for carbohydrates < 65% and protein < 35% of total energy intake. The 2 diets were formulated to be equal in energy (7100 kJ/d; 1700 kcal/d), total fat intake (57 g/d) and fibre (17 g/d). The education guidelines for the CHO group followed the USDA Food Guide Pyramid and emphasised restricting dietary fat and cholesterol with use of breads, rice, cereals, and pasta. Both diets included 5 servings/d of vegetables and 2–3 servings of fruits.

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: PRO diet. Prescribed dietary protein at 1.6 g/kg/d (~30% of energy intake) with a carbohydrate/protein ratio < 1.5 and dietary lipids ~30% energy intake. Recommendation for 30 min of walking 5 d/week. Energy prescription of 7100 kJ/d for women and 7940 kJ/d for men

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: N = 64 in total of which N = 28 males (44%) and N = 36 females (56%), mean (SE) age 45.2 (1.2) years, mean (SE) weight 91.7 (2.0) kg, mean (SE) BMI 32.2 (0.5) kg/m²

Why? Increased protein and reduced carbohydrate diets are often effective, for short-term weight loss. This study investigated the longer-term benefits of a high-protein diet while adding a comprehensive nutrition education and a high level of monitoring. We anticipated that regardless of the compliance definition, the PRO diet would invoke more favourable body composition and blood lipid changes both after active weight loss and through the 12-mo weight loss and maintenance periods.

Layman 2009 (Continued)

What (materials)? "Each diet group received a menu plan with meals for each day meeting established nutritional requirements and dietary fat guidelines. Participants were provided with electronic food scales and were instructed to weigh all food servings at all meals. Participants received specific diet programme instructions from a research dietitian, including the menus, food substitutions, and portion sizes. Physical activity was monitored using daily activity logs and armband accelerometers (Body-Media) worn 3 d/mo. Activity logs were collected each week."

What (procedures)? High-protein, low-carbohydrate diet with comprehensive nutrition education and high levels of monitoring. The PRO diet provided dietary protein at 1.6 g/kg/day (30% of energy intake) with a carbohydrate:protein ratio < 1.5 and dietary lipids roughly 30% energy intake. These diets were designed to fall within the Acceptable Macronutrient Distribution Range (AMDR) of the DRI as established by the Institute of Medicine with minimum Recommended Daily Allowance (RDA) intakes for carbohydrates > 130 g/d and protein > 0.8 g/kg/d and with upper ranges for carbohydrates, 65% and protein, 35% of total energy intake. The 2 diets were formulated to be equal in energy [7.10 MJ/d (1700 kcal/d for females; 7.94 MJ/d (1900/d kcal) for males], total fat intake (30% of energy), and fibre (17 g/4.18 MJ). For the PRO group, the education guidelines emphasised use of high-quality, low-fat proteins including lean meats, reduced-fat dairy, and eggs or egg substitutes. Both diets included 5 vegetable servings/d and 2–3 fruit servings/d. With weekly sessions (60 mins) led by a dietitian. The exercise guidelines emphasised physical activity lifestyle recommendations based on the NIH Guidelines for Weight Management. These guidelines recommend a minimum of 30 min of walking 5 d/wk; however, participation was voluntary.

Who provided? Dietitian

How and where? Face-to-face at the weight management research facility

When and how much? Throughout the 12-mo study, participants were required to attend a 1-h meeting each week.

Strategies to improve or maintain fidelity; tailoring and modification: Group meeting with the research dietitians who provided diet information, answered questions, and reviewed diet records for treatment compliance. Participants were required to report 2 3-d weighed food records during the baseline period prior to assignment to diet groups. Nutrient intakes were evaluated as mean daily intakes from the 3-d weighed records using Nutritionist Pro software (First DataBank) for treatment compliance. Compliance with dietary protocols was also monitored with plasma TAG at 0, 4, and 12 mo as a marker of carbohydrate intake and 24-h urinary urea at 0, 4, and 8 mo as a marker of protein intake. High degree of nutrition monitoring throughout the 12 months with weekly meetings that included monitoring body weight, weighed food records, and diet instruction. 3-d weighed food records, which were reviewed each week with feedback to participants about diet compliance. Any participant with an unexcused absence at a weekly meeting was called by a staff dietitian to promote attendance and any participant with 3 consecutive absences was asked to define their participation status in the study.

Extent of intervention fidelity: All participants completing data collection participated in < 75% of meetings, including weigh-ins and diet records. Compliance with dietary protocols was also monitored with plasma TAG at 0, 4, and 12 mo as a marker of carbohydrate intake and 24-h urinary urea at 0, 4, and 8 mo as a marker of protein intake.

Concomitant interventions: Participants were excluded if they were on lipid-lowering medications, oral steroids or antidepressant medication.

Control diet:

Name (as reported) and brief description: CARB diet. Provided dietary protein equal to 0.8 g/kg/d (~15% of energy intake) with a carbohydrate/protein ratio > 3.5 and total fat ~30% of energy intake. Recommendation for 30 min of walking 5 d/week. Energy prescription of 7100 kJ/d for women and 7940 kJ/d for men

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: N = 66 in total of which N = 31 males (47%) and N = 35 females (53%), mean (SE) age 46.0 (1.0) years, mean (SE) weight 93.8 (1.6) kg, mean (SE) BMI 32.7 (0.5) kg/m².

Layman 2009 (Continued)

Why? NR

What (materials)? "Each diet group received a menu plan with meals for each day meeting established nutritional requirements and dietary fat guidelines. Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 6.63 (1.38)

TG (mmol/L): mean (SD) 1.49 (0.87)

Group differences at baseline: NR

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Numbers of participants missing for lipids and blood pressure at baseline: total cholesterol: intervention 2/53; control 4/57, LDL cholesterol: intervention 4/53; control 6/57, HDL cholesterol: intervention 4/53; control 6/57, triglycerides: intervention 4/53; control 5/57, systolic BP: intervention 5/53; 6/57, diastolic BP: intervention 5/53; control 6/57

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate diet with 34.5% energy from carbohydrates, 35.0% from fat and 29.9% from protein. Energy restriction of 1200 kcal/d

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: Participants were female only with mean (SD) age 50.1 (14.0) years, mean (SD) weight 84.8 (14.1) kg, mean (SD) BMI 32.8 (5.1) kg/m², mean (SD) total cholesterol 6.65 (1.34) mmol/L, mean (SD) LDL 4.46 (1.08) mmol/L, mean (SD) HDL 1.48 (0.35) mmol/L, mean (SD) triglycerides 1.47 (0.83) mmol/L, mean (SD) diastolic BP 86.0 (11.6) mmHg, mean (SD) systolic BP 135.7 (23.8).

Why? Weight management should not focus on weight loss only. There is a need to assess the effects of a low-carbohydrate diet on weight loss and medical outcomes, such as cardiovascular risk factors.

What (materials)? "Written material described the diet in terms of exchanges (meat or alternative, bread, fruit, and allowances for milk and spreads) supported by specially written recipes. Certain foods such as jam or marmalade were included to help compliance."

What (procedures)? 1200 kcal/d diet were designed after pilot studies conducted by negotiation with the research dietitian to determine the lowest and highest proportion of energy from carbohydrate which were acceptable to overweight women similar to those in the study population. A diet with 24% energy from carbohydrate was found unacceptable so the diet was modified to contain 35% carbohydrate

Lean 1997 (Continued)

drate. Subjects were asked to continue with 1200 kcal/d as long as possible, but if more was eaten, to try to use the same diet composition (low-carbohydrate), and proportion of exchanges.

Who provided? Dietitian

How and where? Review at hospital outpatient clinic (mode of delivery not described); telephone contact by the dietitian was used to reduce dropouts.

When and how much? Six weekly intervals for six months (4 sessions)

Strategies to improve or maintain fidelity; tailoring and modification: The diet included certain foods such as jam or marmalade to assist compliance.

Extent of intervention fidelity: NR

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: High-carbohydrate diet with 58.0% energy from carbohydrates, 20.5% from fat and 20.7% from protein. Energy restriction of 1200 kcal/d

Control diet type (carbohydrate-fat-protein): Balanced-balanced-high

Exercise component? No

Recipients: Participants were female only with mean (SD) age 51.1 (13.6) years, mean (SD) weight 83.9 (17.4) kg, mean (SD) BMI 32.3 (5.5) kg/m², mean (SD) total cholesterol 6.63 (1.38) mmol/L, mean (SD) LDL 4.47 (1.03) mmol/L, mean (SD) HDL 1.43 (0.38) mmol/L, mean (SD) triglycerides 1.49 (0.87) mmol/L, mean (SD) diastolic BP 84.2 (12.7) mmHg, mean (SD) systolic BP 136.7 (21.5).

Why? There is a need to assess the effects of a high- carbohydrate diet, as comparator, on weight loss and medical outcomes, such as cardiovascular risk factors.

What (materials)? "Written material described the diet in terms of exchanges (meat or alternative, bread, fruit, and allowances for milk and spreads) supported by specially written recipes. Certain foods such as jam or marmalade were included to help compliance."

What (procedures)? 1200 kcal/d diets were designed after pilot studies conducted by negotiation with the research dietitian to determine the lowest and highest proportion of energy from carbohydrate which were acceptable to overweight women similar to those in the study population. A high CHO diet of 58% energy was found to be acceptable. Subjects were asked to continue with 1200 kcal/d as long as possible, but if more was eaten, to try to use the same diet composition (high or carbohydrate), and proportion of exchanges.

Who provided? Dietitian

How and where? Review at hospital outpatient clinic (mode of delivery not described); telephone contact by the dietitian was used to reduce dropouts.

When and how much? Six weekly intervals for six months (4 sessions)

Other notes about methods: NA

Participants

Country and setting: Australia, outpatient clinic in Adelaide. Uncooked, pre-weighed key foods representative of each diet's macronutrient profile, totalling approximately 65% of energy, were provided to participants every two weeks.

Eligibility criteria: Participants aged between 20 and 65 years, with at least one risk factor for CVD (other than obesity) and BMI between 25 and 40 kg/m². Participants were excluded if they used hypoglycemic medication affecting insulin sensitivity; had a history of heavy alcohol consumption, metabolic or coronary heart disease, type 1 or 2 diabetes, or exercise patterns with large fluctuations; or dined out frequently (more than twice a week) and could not stop. Subjects on beta-blockers, fish oil supplements, cholesterol-lowering medication, prednisolone, steroids and diuretics were instructed to maintain doses of these.

Type 2 diabetes at baseline: No

Impaired glucose tolerance at baseline: No

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Mixed

Other notes about participants: Gender distribution was for all participants randomised.

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Very low-carbohydrate (VLC) diet prescribing 6500 kJ as 35% protein, 60% fat (20% saturated fat) and 4% carbohydrate

Treatment diet type (carbohydrate-fat-protein): Very low-high-high

Exercise component? No

Recipients: Total n = 30 with n = 6 (20%) males and n = 24 (80%) females, mean (SD) age 48.3 (7.6) years, mean (SD) weight 87.6 (2.3) kg, mean (SD) BMI 32.3 (3.1) kg/m², mean (SD) total cholesterol 5.9 (1) mmol/L, mean (SD) HDL 1.3 (0.3) mmol/L, mean (SD) LDL 3.1 (1.7) mmol/L, mean (SD) triglycerides 1.8 (1) mmol/L, mean (SD) glucose 5.4 (0.6) mmol/L, mean (SD) systolic BP 129.8 (15.1) mmHg, mean (SD) diastolic BP 77.2 (13) mmHg

Lim 2010 (Continued)

Why? Very low-carbohydrate diets have been suggested as possibly having greater effectiveness in weight loss and improvements in metabolism than traditional weight loss. No trials have determined the long-term effects of such diets in persons with cardiovascular risks.

What (materials)? Participants were provided with prescriptive meal plans and recipe information. Uncooked, pre-weighed key foods representative of the very low-carbohydrate diet's macronutrient profile, and providing approximately 65% of energy, were provided to participants.

What (procedures)? "The diets had the same energy content (6500 KJ). The planned macronutrient profiles for the diets were: VLC diet (35% of energy as protein, 60% fat, 20% saturated fat, 4% carbohydrate). Participants were provided with prescriptive meal plans and foods contributing to 65% energy of the meal plans. They also received individual dietary counselling every 2 weeks from a qualified dietitian to monitor compliance to their assigned diets. Following the intensive phase, subjects were advised to maintain their allocated energy-restricted diet for an additional 12 months." They were also instructed to keep three-day weighed food records before five follow-up visits.

Who provided? Qualified dietitian provided consultations and analysed three-day weighed food diaries using Diet/1 Nutrition Calculation software (Xyris Software 1998, Highgate Hill, Queensland, Australia).

How and where? Dietary counselling, compliance monitoring and advice for adherence was individual and conducted at the CSIRO outpatient clinic.

When and how much? Key foods were provided every two weeks. Dietary counselling and compliance monitoring was done every two weeks during the first three months; thereafter dietary advice and analysis of three-day food diaries (two weekdays and one weekend day) were done at 3, 6, 9, 12 and 15 months from baseline. Duration of counselling sessions NR

Strategies to improve or maintain fidelity; tailoring and modification: Provision of key foods representative of the diet, compliance monitoring on a fortnightly basis during the first three months of the study, individualised dietary advice on adherence and keeping of three-day weighed food records at 3, 6, 9, 12 and 15 months

Extent of intervention fidelity: NR

Concomitant interventions: Subjects on beta-blockers, fish oil supplements, cholesterol-lowering agents, prednisolone, steroids and diuretics were asked to maintain the doses throughout the study.

Control diet:

Name (as reported) and brief description: High-unsaturated fat (HUF) diet prescribing 6500 kJ as 20% protein, 30% fat (6% saturated fat and 8% polyunsaturated fat) and 50% carbohydrate

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Total n = 30 with n = 6 (20%) males and n = 24 (80%) females, mean (SD) age 47.2 (10.5) years, mean (SD) weight 93.0 (2.8) kg, mean (SD) BMI 34.6 (3.7) kg/m², mean (SD) total cholesterol 6.1 (1.1) mmol/L, mean (SD) HDL 1.3 (0.3) mmol/L, mean (SD) LDL 3 (2.1) mmol/L, mean (SD) triglycerides 1.6 (0.6) mmol/L, mean (SD) glucose 5.4 (0.6) mmol/L, mean (SD) systolic BP 130.9 (12.1) mmHg, mean (SD) diastolic BP 79.8 (8.3) mmHg

Why? Weight loss is associated with lowered cardiovascular risk, such as lowering of blood pressure and serum lipids. Traditional approaches have been to advise a high-carbohydrate low-fat diet.

What (materials)? Participants were provided with prescriptive meal plans and recipe information. Uncooked, pre-weighed key foods representative of the very low-carbohydrate diet's macronutrient profile, and providing approximately 65% of energy, were provided to participants.

What (procedures)? Participants were instructed to follow the high-unsaturated fat diet, comprising 50% carbohydrate, 20% protein and 30% fat (6% saturated and 8% polyunsaturated), according to provided materials. They were also instructed to keep three-day weighed food records before five follow-up visits.

Liu 2013
Study characteristics

Methods

Review comparison(s) addressed by this study: 1

Study design: RCT, parallel, single-centre (1)

Trial registry number: NCT01358890

Total number of trial arms: 2

Year trial started: 2011

Sample size calculation: Yes

Outcome(s) used for sample size calculation: Difference in high-density lipoprotein (HDL) cholesterol

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 12 weeks

What was the duration of the weight maintenance phase: NA

Other notes about methods: Participants were randomised after stratification by age.

Participants

Country and setting: China, outpatient institute for nutritional sciences at a hospital in Shanghai. Meals were prepared in a designated kitchen at the hospital; participants received these meals daily and had them in a designated dining room.

Eligibility criteria: Participants were women aged 30 to 65 years with BMI ≥ 24 kg/m². Participants were excluded if they were pregnant or lactating; had a history of cardiovascular disease, cancer, mental disorders or gastrointestinal disease which would prevent compliance; had gastrointestinal surgery previously, with the exception of hernia or appendicitis; currently used antidepressants; had plasma glutamic-pyruvic transaminase, glutamic-oxaloacetic transaminase, creatinine or urea N within specified ranges; were participating in other research studies in the past three months or had liver or renal biomarkers beyond reference levels.

Type 2 diabetes at baseline: Unclear; stratified with non-T2DM since baseline fasting blood glucose levels in both groups were not indicative of diabetes.

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Female

Total number randomised: 50

Total attrition in trial: 2

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Participants were Chinese and BMI cut-offs are lower for this population.

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate ad libitum diet. Designed to provide 20 g carbohydrate daily in the first week, with a gradual increase to 120 g by adding 10 g weekly until the 11th week.

Treatment diet type (carbohydrate-fat-protein): Very low4w to low11w-unclear-unclear

Exercise component? No

Recipients: Women only N = 25 mean (SE) weight 64.8 (1.3) kg, mean (SE) BMI 26.6 (0.5).

Why? Unclear if Chinese people, given their habitually high-carbohydrate consumption, are able to adapt to a LC diet for weight control. This study investigated the adherence to a LC diet on weight loss and its effects on the improvement of cardiovascular risk factors among overweight or obese Chinese women, in comparison with an energy-restricted (ER) diet.

What (materials)? "All experimental meals were prepared in a designated kitchen at the hospital. All participants received their experimental meals every day including weekends."

What (procedures)? The LC diet was designed to provide 20 g carbohydrate daily in the first week, with a gradual increase to 120 g, by adding 10 g weekly until the 11th week, since carbohydrate intake up to 120 g/d has been reported to be sufficient to benefit weight control and metabolic profiles. In addition, a ketogenic diet with no more than 50 g carbohydrate might be rather difficult for a population with a habitually high-carbohydrate intake. Carbohydrate-rich foods, such as white rice, steamed bread and tubers, were substituted with fish, poultry and plant oil. In addition to three meals, snacks, including boiled eggs (with or without yolk), cucumbers and tomatoes, were also provided ad libitum any time from 06.00 to 17.30 hours each day. Participants were encouraged to consume every meal in a designated dining room within the building where they worked. Sometimes the participants also consumed meals close to their working place in the hospital if they had a short lunch break. In this case, the participants were required to report to dietitians about any leftovers or intake of foods other than the experimental meals. At the beginning of the intervention, participants were instructed to maintain their usual physical activity levels throughout the study; those in the LC diet group were particularly recommended to drink plenty of plain water, to compensate for possible water loss in ketosis.

Who provided? Dietitian

How and where? Face-to-face at a hospital in Shanghai

When and how much? Daily monitoring of intake

Strategies to improve or maintain fidelity; tailoring and modification: "All meals were prepared and consumed on the hospital premises. Any leftovers were reported to the dietitian. Dietary compliance was evaluated by using food diaries and measuring urinary ketones. Hunger levels and overall diet acceptance were assessed through self-reports. At weeks 6 and 12, intakes of energy and nutrients were evaluated through a combined analysis of meal menus and a 7-d food diary recorded by a dietitian. Energy and nutrients were calculated using Nutrition Star Software (Zhending Company Limited), in accordance with the Chinese food composition table."

Extent of intervention fidelity: At baseline, intakes of energy and nutrients were obtained through a 3-d food diary. At the end of the intervention, a five-point Likert scale (20,21) was used to evaluate the hunger level at each month of the intervention.

Liu 2013 (Continued)

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Energy-restricted diet. Traditional Chinese style with target total energy intake of 5021 kJ/d; energy from carbohydrate, protein and fat was 50 to 55%, 17 to 19% and 26 to 33%. Energy prescription with an initial target for a total energy intake of 5021 kJ/d and adjusted to 6276 kJ/d due to extreme hunger reported by some participants

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: NR

Why? A higher-carb energy-restricted diet should be more acceptable in the Chinese population for weight loss.

What (materials)? "All experimental meals were prepared in a designated kitchen at the hospital. All participants received their experimental meals every day including weekends."

What (procedures)? The ER diet was designed in the traditional Chinese style with an initial target for a total energy intake of 5021 kJ/d (1200 kcal/d). Energy from carbohydrate, protein and fat in the ER diet was 50–55, 17–19 and 26–33 %, respectively. Participants were encouraged to consume every meal in a designated dining room within the building where they worked. Sometimes the participants also consumed meals close to their working place in the hospital if they had a short lunch break. In this case, the participants were required to report to dietitians about any leftovers or intake of foods other than the experimental meals. At the beginning of the intervention, participants were instructed to maintain their usual physical activity levels throughout the study. All the main meals and snacks were prepared/provided by the hospital kitchen daily including weekends over a period of 12 weeks.

Who provided? Dietitian

How and where? Face-to-face at a hospital in Shanghai

When and how much? Daily monitoring of intake

Strategies to improve or maintain fidelity; tailoring and modification: "All meals were prepared and consumed on the hospital premises. Any leftovers were reported to the dietitian. Study characteristics

Methods

Review comparison(s) addressed by this study: 1

Study design: RCT, parallel, single-centre (1)

Trial registry number: NCT02559479

Total number of trial arms: 2

Year trial started: 2015

Sample size calculation: Yes

Outcome(s) used for sample size calculation: HOMA-IR

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 6 months

Marco-Benedi 2019 (Continued)

What was the duration of the weight maintenance phase: NA

Other notes about methods: NA

Participants

Country and setting: Spain, outpatient university hospital unit in Zaragoza

Eligibility criteria: Participants aged 18 to 70 with a BMI ranging from 27.5 to 40 kg/m² and a steady weight in the previous two months, with a diagnosis of impaired fasting glucose or type 2 diabetes defined as fasting glucose concentration over 100 mg/dL and/or HbA1c over 5.7% and taking no anti-diabetic drugs; or taking a stable dose of metformin for the past two months (regardless of glucose or HbA1c levels). Participants were excluded if their HbA1c level at baseline exceeded 7%; if they used lipid-lowering medication and/or sterol supplements, omega 3 fatty acids, weight-loss medication; had kidney disease (according to specified glomerular filtration rate), active liver disease or uncontrolled hypothyroidism; or any other condition which could threaten compliance.

Type 2 diabetes at baseline: Mixed; stratified with non-T2DM since even though inclusion criteria were diagnosis of impaired fasting glucose or diabetes, baseline HbA1c in both groups was not indicative of T2DM.

Impaired glucose tolerance at baseline: Mixed

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Mixed

Total number randomised: 80

Total attrition in trial: 13

Treatment diet

Participants randomised: 40

Participants withdrawn (voluntary): 5

Total attrition: 5

Control diet:

Participants randomised: 40

Participants withdrawn (voluntary): 8

Total attrition: 8

Baseline data treatment diet:

Randomised participants not included: 2/40

Age (years): mean (SD) 56.5 (8.59)

Gender distribution (as reported): female 18/38 (47.4%), male 20/38 (52.6%)

Weight (kg): mean (SD) 91.4 (12.7)

BMI (kg/m²): mean (SD) 33.2 (3.63)

DBP (mmHg): mean (SD) 86.9 (9.86)

SBP (mmHg): mean (SD) 134 (14.5)

HbA1c (%): mean (SD) 6.38 (1.00)

LDL (mmol/L): mean (SD) 3.52 (0.98)

HDL (mmol/L): mean (SD) 1.41 (0.31)

Marco-Benedi 2019 (Continued)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.80 (1.23)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.57 (1.00)

TG (mmol/L): mean (SD) 2.08 (0.99)

Group differences at baseline: Yes

Characteristic(s) with significant group difference and relevant statistic: characteristic 1 : visceral fat (P = 0.019); intervention vs control arm; characteristic 2: physical activity level (P = 0.046); intervention vs control arm

Other notes about participants: NA

 Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Food typical of the Mediterranean diet with macronutrient distribution of 35% protein, 30% fat and 35% carbohydrates. 80% of protein came from lean animal sources. Heterogeneous physical activity advice based on participant condition. Total number of calories prescribed was calculated using the Harris-Benedict equation and applying an activity factor and a daily 2510 kJ deficit.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: Persons with impaired fasting glucose or diabetes, 47.4% male, aged 56.5 (8.59) years with BMI 33.2 (3.63) and weight 91.4 (12.7) kg

Why? An energy-restricted diet with high protein content may improve insulin resistance in persons with type 2 diabetes, and achieve great weight loss than standard protein diets.

What (materials)? Daily menus for high-protein diet

Marco-Benedi 2019 (Continued)

What (procedures)? Participants were instructed to follow a high-protein diet, with dietitians providing follow-up consultations to reinforce the intervention. When certain weight loss targets were achieved, calories were further reduced by 100 to 200 kcal to compensate for the change in basal metabolic rate. Three-day weighed food records were kept to focus participants on the intervention. Dietitians performed individual consultations every 2 weeks to reinforce the intervention and to motivate weight loss.

Who provided? Dietitians provided follow-up consultations.

How and where? Consultations were per individual. Location of these sessions NR

When and how much? The duration of the intervention was 6 months, with follow-up consultations every two weeks. Three-day weighed food records were kept before study visits at three and six months.

Strategies to improve or maintain fidelity; tailoring and modification: Consultations every two weeks to reinforce the intervention, measurement of body weight at three and six months, three-day weighed food record before each of these visits. Diet compliance was assessed by self-reported questionnaire and urea nitrogen concentrations were determined from urine sample.

Extent of intervention fidelity: Urine urea/weight (kg) ratio was increased by 10.2 (99.6)% at three months and 33.3 (71.9)% at six months. Blood urea increased more in high-protein dieters when compared to standard-protein dieters ($P = 0.007$ at three months and 0.029 at six months). The authors inferred correct adherence from these data.

Concomitant interventions: A total of 35.1% of participants were on metformin.

Control diet:

Name (as reported) and brief description: Food typical of the Mediterranean diet with macronutrient distribution of 18% protein, 30% fat and 52% carbohydrates. 80% of protein came from lean animal sources. Heterogeneous physical activity advice based on participant condition. Total number of calories prescribed was calculated using the Harris-Benedict equation and applying an activity factor and a daily 2510 kJ deficit.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: Persons with impaired fasting glucose or diabetes, 34.3% male, aged 54.6 (8.11) years with BMI 32.3 (3.70) and weight 86.3 (11.8) kg.

Why? Weight loss is the first-order treatment for type 2 diabetes, with loss of adipose tissue most efficient in improving insulin resistance.

What (materials)? Daily menus for standard-protein diet

What (procedures)? Participants were instructed to follow a standard-protein diet, with dietitians providing follow-up consultations to reinforce the intervention. When certain weight loss targets were achieved, calories were further reduced by 100 to 200 kcal to compensate for the change in basal metabolic rate. Three-day weighed food records were kept to focus participants on the intervention. Dietitians performed individual consultations every 2 weeks to reinforce the intervention and to motivate weight loss.

Who provided? Dietitians provided follow-up consultations.

Marco-Benedi 2019 (Continued)

weighed food record before each of these visits. Diet compliance was assessed by self-reported questionnaire and urea nitrogen concentrations were determined from urine sample.

Extent of intervention fidelity: Urine urea/weight (kg) ratio was decreased by 23.6 (104)% at three months and 6.99 (66.7)% at six months. The authors inferred correct adherence from these data.

Concomitant interventions: A total of 36.4% of participants were on metformin.

Outcomes

Change in body weight (kg) at 3 to <12 months: Yes

Change in body weight (kg) at ≥12 months: No

Number of participants with 5% weight loss from baseline at 3 to <12 months: No

Number of participants with 5% weight loss from baseline at ≥12 months: No

Change in BMI (kg/m²) at 3 to 12 months: Yes

Change in BMI (kg/m²) at ≥12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥12 months: No

Change in DBP (mmHg) at ≥12 months: No

Change in SBP (mmHg) at ≥12 months: No

All-cause mortality at ≥12 months: No

Cardiovascular mortality at ≥12 months: No

Non-fatal myocardial infarction at ≥12 months: No

Non-fatal stroke at ≥12 months: No

Diagnosis of type 2 diabetes mellitus at ≥12 months: No

Change in HbA1c (%) at ≥12 months: No

Change in LDL (mmol/L) at ≥12 months: No

Change in HDL (mmol/L) at ≥12 months: No

Change in non-HDL (mmol/L) at ≥12 months: No

Change in total cholesterol (TC) (mmol/L) at ≥12 months: No

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥12 months: No

Participant-reported adverse effects: No

 Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Diet comprised 35% protein, 30% fat and 35% carbohydrates with exercise recommendations. Each participant's caloric prescription represented a deficit of 600 kcal/day as calculated from energy intakes estimated by multiplying the activity factor by the resting energy expenditure calculated with the Harris-Benedict equation.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Mateo-Gallego 2017 (Continued)

Exercise component? Yes

Recipients: 30 females only with mean (SD) weight (kg) 85.1 (8.39), mean (SD) systolic BP 119 (12.6), mean (SD) diastolic BP 79.3 (9.58), mean (SD) total cholesterol 217 (37.8) mg/dL, mean (SD) LDL 132 (29.9) mg/dL, mean (SD) HDL 59.9 (14.3) mg/dL, mean (SD) triglycerides 124 (49.8) mg/dL, mean (SD) glucose 85.9 (8.26) mg/dL, mean (SD) HbA1c 5.42 (0.28)%

Why? High-protein energy-restricted diets have demonstrated efficacy in promoting weight loss in overweight and obesity. However, the protein percentage that achieves optimal efficacy and acceptability remains unknown. We sought to assess the effects of three energy-reduced diets with different percentages of calories from protein (20%, 27%, and 35%) on weight loss and lipids.

What (materials)? Recipes

What (procedures)? The diet had the following distribution of calories: protein, 35%; carbohydrates, 35%; fat, 30% in all diets.

Who provided? Dietitian

How and where? Individual, face-to-face, location NR

When and how much? Every two weeks individual meetings with dietitian for 3 months

Strategies to improve or maintain fidelity; tailoring and modification: The dietitian provided participants with recipes and shopping counselling to improve intervention compliance and to achieve weight-loss goals. A single dietitian performed individual consultations every 2 weeks to reinforce the intervention and to motivate weight loss. Participants were asked to complete a 3-day weighted food record before each visit.

Extent of intervention fidelity: Dietary compliance and physical activity were assessed through self-reported questionnaires. Compliance was defined as protein consumption within $\pm 3\%$ of the prescribed quantity. Twenty-seven of the 27 (100.0%) women who completed the intervention at three months were defined as compliant. At the end of the intervention, mean macronutrient intakes were 37.9% (SD 5.38) carbohydrates, 31.8% (SD 5.19) fat and 30.4% (SD 6.58) protein; mean energy intake was 1172 kcal (range of 1107 to 1226 kcal), representing a 31.0% (SD 21.8) reduction from baseline.

Concomitant interventions: The use of lipid-lowering or anti-diabetic medications, phytosterols, omega-3 fatty acids or any obesity medication was an exclusion criterion.

Control diet:

Name (as reported) and brief description: Diet comprised 20% protein, 30% fat and 50% carbohydrates with exercise recommendations. Each participant's caloric prescription represented a deficit of 600 kcal/day as calculated from energy intakes estimated by multiplying the activity factor by the resting energy expenditure calculated with the Harris-Benedict equation.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: Recipients were 100% female, aged 43.7 (9.74) years old, weighed mean (SD) 86.4 (8.35) kgs with a mean (SD) BMI 33.2 (3.31).

Why? High-protein energy-restricted diets have demonstrated efficacy in promoting weight loss in overweight and obesity. However, the protein percentage that achieves optimal efficacy and acceptability remains unknown. We sought to assess the effects of three energy-reduced diets with different percentages of calories from protein (20%, 27%, and 35%) on weight loss and lipids.

What (materials)? Recipes

What (procedures)? The diet had the following distribution of calories: protein, 20%; carbohydrates, 50%; fat, 30%.

Who provided? Dietitian

Mateo-Gallego 2017 (Continued)

How and where? Individual, face-to-face, location NR

When and how much? Every two weeks individual meetings with dietitian for 3 months

Strategies to improve or maintain fidelity; tailoring and modification: The dietitian provided participants with recipes and shopping counselling to improve intervention compliance and to achieve weight-loss goals. A single dietitian performed individual consultations every 2 weeks to reinforce the intervention and to motivate weight loss. Participants were asked to complete a 3-day weighted food record before each visit.

Extent of intervention fidelity: Dietary compliance and physical activity were assessed through self-reported questionnaires. Compliance was defined as protein consumption within $\pm 3\%$ of the prescribed quantity. Twenty-one of the 24 (87.5%) women who completed the intervention at three months were defined as compliant. At the end of the intervention, mean macronutrient intakes were 44.6% (SD 5.37) carbohydrates, 31.7% (SD 5.46) fat and 23.4% (SD 1.76) protein; mean energy intake was 1179 kcal (range of 1151 to 1241 kcal), representing a 34.8% (SD 20.9) reduction from baseline.

Concomitant interventions: The use of lipid-lowering or anti-diabetic medications, phytosterols, omega-3 fatty acids or any obesity medication was an exclusion criterion.

Outcomes

Mellberg 2014 (Continued)

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Unrestricted/ad libitum prescription in both diets

Treatment diet:

Name (as reported) and brief description: Paleolithic diet (PD) providing 30% of energy from protein, 40% from fat (with high intake of MUFA and PUFA) and 30% from carbohydrates. Consumed ad libitum

Treatment diet type (carbohydrate-fat-protein): Low-high-high

Exercise component? No

Recipients: N = 35 (100%) women with mean (SD) age 59.5 (5.5) years, mean (SD) body weight 87.0 (10.6) kg, mean (SD) BMI 32.7 (3.6) kg/m²

Why? " PD would be more efficient than a conventional low-fat/high-fibre diet at reducing fat mass during a 2-year randomized dietary intervention trial in obese postmenopausal women."

What (materials)? "The subjects were given recipes and written instructions to facilitate the preparation of meals at home."

What (procedures)? The PD provided 30% of energy intake (E%) from protein, 40 E% fat, and 30 E% carbohydrates and included a recommendation for a high intake of MUFA and polyunsaturated fatty acids (PUFA). The diet was based on lean meat, fish, eggs, vegetables, fruits, berries, and nuts. Dairy products, cereals, added salt, and refined fats and sugar were excluded. The group sessions consisted of information on and cooking of the intervention diets, dietary effects on health, behavioural changes, and group discussions. The subjects were given recipes and written instructions to facilitate the preparation of meals at home. Eight group sessions (four cooking classes and four follow-up sessions) were held during the first 6 months of the intervention. Additional group meetings were held at 9, 12, 18, and 24 months.

Who provided? One dietitian per study arm

How and where? Face-to-face, location NR

When and how much? 12 group sessions throughout 24-month period

Strategies to improve or maintain fidelity; tailoring and modification: Dietary intake was assessed using 4-day estimated self-reported food records conducted at baseline (2 × 4 days) and monthly until 6 months, thereafter at 9, 12, 18 and 24 months. Subjects were instructed to keep a record of all food items consumed over four consecutive days (three weekdays and one weekend day) and to describe and estimate the amount of food eaten by using coloured food-portion photographs representing known weights and household measuring utensils (e.g. cup, spoon, and standard weight of food items). The reported food intake was converted to estimates of energy and nutrient intake using the nutritional analysis package Dietist XP (version 3.0) based on the food composition database of the Swedish National Food Administration (2008-03-06). Nitrogen excretion in urine (NU) was used as a biomarker for protein intake, with three 24-h urine samples collected at baseline and after 6 and 24 months. The para-aminobenzoic acid (PABA) method 14 was used to verify the completeness of the urine collections. NU was determined using the Kjeldahl technique with a Kjeltex analyser (model NMKL nr 6, Eurofins Food & Agro AB, Lidköping, Sweden).

Extent of intervention fidelity: The PD group reported a significantly lower intake (E% and g/d) of carbohydrates, higher intake (E% and g/d) of protein, MUFA, PUFA, cholesterol, and higher total fat (E%), MUFA:SFA and PUFA:SFA ratios compared to the NNR group. The PD group reported a more pronounced change in the ratio (E%) protein:carbohydrates:total fat from baseline to 6 and 24 months (17:46:33, 23:29:44, 22:34:40; respectively) compared to the NNR group (17:45:35, 19:48:32, 17:43:34; respectively). Target intakes were not fully achieved; the PD did not reach the target amounts of percent energy of protein (30 E%) at 6 and 24 months, and the NNR group did not reach the target amounts of carbohydrates (55-60%).

Concomitant interventions: NR

Mellberg 2014 (Continued)

Control diet:

Name (as reported) and brief description: Nordic Nutrition Recommendations (NNR) diet aimed for an energy intake comprising 15% protein, 25 to 30% fat and 55-60% carbohydrates, with emphasis on low-fat dairy products and high fibre. Consumed ad libitum

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 35 (100%) women with mean (SD) age 60.3 (5.9) years, mean (SD) body weight 86.8 (10.0) kg, mean (SD) BMI 32.6 (3.3) kg/m²

Why? NR

What (materials)? "We developed a 2-wk menu plan for each group with meals for each day meeting established nutritional requirements and lipid guidelines." Participants also received food scales.

What (procedures)? The NNR diet was aiming at a daily intake of 15 E% protein, 25-30 E% fat, and 55-60 E% carbohydrates, with emphasis on low-fat dairy products and high-fibre products. The group sessions consisted of information on and cooking of the intervention diets, dietary effects on health, behavioural changes, and group discussions. The subjects were given recipes and written instructions to facilitate the preparation of meals at home. Eight group sessions (four cooking classes and four follow-up sessions) were held during the first 6 months of the intervention. Additional group meetings were held at 9, 12, 18, and 24 months.

Who provided? One dietitian per study arm

How and where? Face-to-face, location NR

When and how much? 12 group sessions throughout 24 month period

Strategies to improve or maintain fidelity; tailoring and modification: Dietary intake was assessed using 4-day estimated self-reported food records conducted at baseline (2 × 4 days) and monthly until 6 months, thereafter at 9, 12, 18 and 24 months. Subjects were instructed to keep a record of all food items consumed over four consecutive days (three weekdays and one weekend day) and to describe and estimate the amount of food eaten by using coloured food-portion photographs representing known weights and household measuring utensils (e.g. cup, spoon, and standard weight of food items). The reported food intake was converted to estimates of energy and nutrient intake using the nutritional analysis package Dietist XP (version 3.0) based on the food composition database of the Swedish National Food Administration (2008-03-06). Nitrogen excretion in urine (NU) was used as a biomarker for protein intake, with three 24-h urine samples collected at baseline and after 6 and 24 months. The para-aminobenzoic acid (PABA) method 14 was used to verify the completeness of the urine collections. NU was determined using the Kjeldahl technique with a Kjeltac analyser (model NMKL nr 6, Eurofins Food & Agro AB, Lidköping, Sweden).

Extent of intervention fidelity: The PD group reported a significantly lower intake (E% and g/d) of carbohydrates, higher intake (E% and g/d) of protein, MUFA, PUFA, cholesterol, and higher total fat (E%), MUFA:SFA and PUFA:SFA ratios compared to the NNR group. The PD group reported a more pronounced change in the ratio (E%) protein:carbohydrates:total fat from baseline to 6 and 24 months (17:46:33, 23:29:44, 22:34:40; respectively) compared to the NNR group (17:45:35, 19:48:32, 17:43:34; respectively). Target intakes were not fully achieved; the PD did not reach the target amounts of percent energy of protein (30 E%) at 6 and 24 months, and the NNR group did not reach the target amounts of carbohydrates (55-60%).

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein diet with placebo supplementation (HP) prescribing 27% protein, 43% carbohydrates and 30% fat. Energy deficit of 500 kcal per day

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: N = 21 women and N = 22 men with mean (SD) age 32.0 (6.82) years, mean (SD) weight 81.8 (12.59) kg, mean (SD) BMI 29.6 (3.02) kg/m², none had existing diabetes or hypertension and all had normal renal, liver and thyroid function.

Why? The diet was included as a comparator for a standard-protein diet with branched-chain amino acids (BCAAs) supplementation. High-protein diets are stated as reducing the loss of lean mass during weight loss, but they are expensive.

What (materials)? Participants were prescribed a hypocaloric diet with a deficit of 500 kcal per day. "To encourage compliance, subjects had prescribed meals provided and delivered to their homes weekly..." "Weekly food delivery for a 6-d food supply was provided for the first 4 wk. Subjects had 1 "free day" each week of their own food. For the subsequent 12 wk, only lunch and dinner meals and snacks were provided for 6 d per wk." Participants were also provided with food checklists with their

Ooi 2021 (Continued)

weekly food delivery, to check off food and record additional food and beverages they consumed. Accelerometers were provided to participants at week 0 and week 8 visits.

What (procedures)? The high-protein diet consisted of 16 weeks following a diet with a macronutrient composition of 30% fat, 43% carbohydrate and 27% protein; with placebo supplementation (as opposed to BCAAs). Diet counselling sessions were provided and participants were called to assess and encourage compliance.

Who provided? A dietitian provided the counselling sessions and called participants.

How and where? Face-to-face counselling sessions were provided; the location of sessions, and whether these were group or individual sessions, was not reported. Participants were called to improve compliance.

When and how much? Counselling sessions were provided at visits at 0, 4, 8, 12 and 16 weeks; duration of sessions was not reported. Participants were called on a fortnightly basis; duration not reported.

Strategies to improve or maintain fidelity; tailoring and modification: Prescribed meals were provided and delivered to encourage compliance, food checklists were used to document dietary compliance, counselling sessions and regular phone calls from the dietitian were used to assess and encourage compliance. Where certain foods could not be consumed by a participant, the dietitian would substitute with foods of a similar composition to adhere to prescribed energy and macronutrients.

Extent of intervention fidelity: Urinary urea:creatinine ratio was used as a surrogate for protein intake and dietary compliance. This increased in the treatment group during the weight loss phase, indicating compliance. Food checklists showed modest deviations from dietary prescription, indicating acceptable compliance.

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Standard-protein diet with placebo supplementation (control, CT) prescribing 14% protein, 56% carbohydrates and 30% fat. Energy deficit of 500 kcal per day

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: N = 24 women and N = 20 men with mean (SD) age 33.5 (7.89) years, mean (SD) weight 80.1 (10.61) kg, mean (SD) BMI 29.3 (2.39) kg/m², none had existing diabetes or hypertension and all had normal renal, liver and thyroid function.

Why? The diet was included as a control for an identical diet with branched-chain amino acids (BCAAs) supplementation. The latter is hypothesised to improve lean mass preservation over a standard-protein diet without supplementation.

What (materials)? Participants were prescribed a hypocaloric diet with a deficit of 500 kcal per day. "To encourage compliance, subjects had prescribed meals provided and delivered to their homes weekly..." "Weekly food delivery for a 6-d food supply was provided for the first 4 wk. Subjects had 1 "free day" each week of their own food. For the subsequent 12 wk, only lunch and dinner meals and snacks were provided for 6 d per wk." Participants were also provided with food checklists with their weekly food delivery.

What (procedures)? The standard-protein diet consisted of 16 weeks following a diet with a macronutrient composition of 30% fat, 56% carbohydrate and 14% protein; with placebo supplementation (as opposed to BCAAs). Diet counselling sessions were provided and participants were called to assess and encourage compliance.

Who provided? A dietitian provided the counselling sessions and called participants.

How and where? Face-to-face counselling sessions were provided; the location of sessions, and whether these were group or individual sessions, was not reported. Participants were called to improve compliance.

Ooi 2021 (Continued)

When and how much? Counselling sessions were provided at visits at 0, 4, 8, 12 and 16 weeks; duration of sessions was not reported. Participants were called on a fortnightly basis; duration not reported.

Strategies to improve or maintain fidelity; tailoring and modification: Prescribed meals were provided and delivered to encourage compliance, food checklists were used to document dietary compliance, counselling sessions and regular phone calls from the dietitian were used to assess and encourage compliance. Where certain foods could not be consumed by a participant, the dietitian would substitute with foods of a similar composition to adhere to prescribed energy and macronutrients.

Parr 2016 (Continued)

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High dairy protein, moderate CHO (HDPMC). ~30% protein, 40% carbohydrate, 30% fat; 4+ dairy servings/day of unsweetened/artificially sweetened, full-fat products. Resistance exercise 3 days per week. Dietary energy restriction of ~250 kcal/day from estimated maintenance energy requirements

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? Yes

Recipients: Overweight and obese participants, 72.4% female, aged mean (SD) 47.0 (5.9), with mean (SD) BMI 32.6 (3.9), mean (SD) weight of 91.7 (6.12) kg

Why? When compared to higher-carbohydrate diets, higher-protein reduced-carbohydrate diets minimise the loss of lean mass during weight loss in the absence of exercise. The inclusion of dairy protein has been associated with a greater decrease in fat mass than those who do not incorporate dairy.

What (materials)? A prescribed menu consisting of three meals per day and a “Dairy/Snack Basket”. Two dairy servings of unsweetened/ artificially sweetened full-fat products from the basket were to be consumed post-exercise training. Educational resources were provided to participants by the dietitian at follow-up visits (not described). Participants received measuring cups and spoons to use throughout the study to assist with recording of portion sizes of their food and drink intake.

What (procedures)? Free-living energy restricted eating plan according to a restriction of 2250 kcal/day from estimated maintenance energy requirements, and required macronutrient composition (30% protein, 40% CHO, 30% fat). Dietary intervention followed a transition from a prescribed menu plan (weeks 0 to 8) to a flexible self-chosen plan (weeks 9 to 16) based on a points system. Participants were prescribed a high dairy protein and moderate carbohydrate diet, as well as supervised resistance exercise, and were provided with dietary advice, educational resources, menus, meal plans and individualised training programmes. Participants were instructed, verbally and in writing, how to complete 7-day food diaries. Daily checklists were conducted; not clear whether this was self-reported.

Who provided? Dietitians met with participants to discuss menus and food choices as well as assess daily checklists. Resistance exercise was supervised by study trainers.

How and where? Meetings with dietitian and exercise supervisor were face-to-face. Location and mode of delivery (group or individual) NR

When and how much? Food checklists were performed daily, meetings with dietitian were fortnightly, duration NR. Seven-day food records were assessed at baseline and weeks 1, 4, 8, 12 and 16. Supervised resistance exercise was undertaken 3 days per week, with participants completing aerobic exercise (walking, cycling or swimming) on other days. Resistance exercise was increased every four weeks. Duration of exercise sessions NR

Strategies to improve or maintain fidelity; tailoring and modification: Dietary non-compliance defined as exceeding prescribed energy restriction by > 200 kcal/day or demonstrating an inability or unwillingness to adhere to the “Dairy/Snack Baskets” and the desired macronutrient manipulation. Compliance to each dietary intervention was assessed by the study dietitian via daily checklists and completion of 7-day food diaries (at weeks 1, 4, 8, 12 and 16). Being non-compliant to the REX was defined as missing > 2 consecutive training sessions. REXs were increased every 4 wks after further 1RM testing. Exercise diaries were kept by study trainers.

Extent of intervention fidelity: Five of 39 participants did not comply with diet and/or exercise. Non-compliance was defined as exceeding restriction by > 200 kcal per day, not adhering to dairy/snack 'baskets' or macronutrient manipulation, or missing > 2 consecutive exercise sessions.

Concomitant interventions: Participants using prescription medication for blood pressure and/or cholesterol, depression, anxiety and arthritis for ≥ 3 months were included. Nutritional supplements were discontinued before the commencement of the trial.

Parr 2016 (Continued)

Control diet:

Name (as reported) and brief description: High-dairy protein, high CHO (HDPHC). ~30% protein, 55% carbohydrate, 15% fat; 4+ dairy servings/day of sweetened, low-fat products. Resistance exercise 3 days per week. Dietary energy restriction of ~250 kcal/day from estimated maintenance energy requirements

Control diet type (carbohydrate-fat-protein): Balanced-low-high

Exercise component? Yes

Recipients: Overweight and obese participants, 68.8% female, aged mean (SD) 47.1 (5.7), with mean (SD) BMI 32.1 (3.6), mean (SD) weight 90.3 (9.9) kg

Why? It is not clear how changes in the carbohydrate to fat ratio within an energy-restricted diet affect loss of lean mass.

What (materials)? A prescribed menu consisting of three meals per day and a “Dairy/Snack Basket”. Two dairy servings of unsweetened/artificially sweetened full-fat products from the basket were to be consumed post-exercise training. Educational resources were provided to participants by the dietitian at follow-up visits (not described). Participants received measuring cups and spoons to use throughout the study to assist with recording of portion sizes of their food and drink intake.

What (procedures)? Participants were prescribed a high-dairy protein and high-carbohydrate diet (30% protein, 55% CHO, 15% fat), as well as supervised resistance exercise, and were provided with dietary advice, educational resources, menus, meal plans and individualised training programmes. Participants were instructed, verbally and in writing, how to complete 7-day food diaries. Daily checklists were conducted; not clear whether this was self-reported.

Who provided? Dietitians met with participants to discuss menus and food choices as well as assess daily checklists. Resistance exercise was supervised by study trainers.

How and where? Meetings with dietician and exercise supervisor were face-to-face. Location and mode of delivery (group or individual) NR

When and how much? Food checklists were performed daily, meetings with dietitian were fortnightly, duration NR. Seven-day food records were assessed at baseline and weeks 1, 4, 8, 12 and 16. Supervised resistance exercise was undertaken 3 days per week, with participants completing aerobic exercise (walking, cycling or swimming) on other days. Resistance exercise was increased every four weeks. Duration of exercise sessions NR

Strategies to improve or maintain fidelity; tailoring and modification: Dietary non-compliance defined as exceeding prescribed energy restriction by > 200 kcal/day or demonstrating an inability or unwillingness to adhere to the “Dairy/Snack Baskets” and the desired macronutrient manipulation. Compliance to each dietary intervention was assessed by the study dietitian via daily checklists and completion of 7-day food diaries (at weeks 1, 4, 8, 12 and 16). Being non-compliant to the REX was defined as missing > 2 consecutive training sessions. REXs were increased every 4 wks after further 1RM testing. Exercise diaries were kept by study trainers.

Extent of intervention fidelity: Three of 40 participants did not comply with diet and/or exercise. Non-compliance was defined as exceeding restriction by > 200 kcal per day, not adhering to dairy/snack 'baskets' or macronutrient manipulation, or missing > 2 consecutive exercise sessions.

Concomitant interventions: Participants using prescription medication for blood pressure and/or cholesterol, depression, anxiety and arthritis for ≥ 3 months were included. Nutritional supplements were discontinued before the commencement of the trial.

TG (mmol/L): mean (SE) 2.0 (0.2)

Group differences at baseline: Yes

Characteristic(s) with significant group difference and relevant statistic: iGFR (P = 0.03); intervention vs control arm as well as albumin excretion rate (P = 0.02); intervention vs control arm

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein diet. Planned protein:fat:carbohydrate ratio was 30:30:40 total energy with a range of protein intake of 90-120 g/d. Saturated fat intake was 10% TE; energy limited to 6000 kJ/day.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: Participants were 28.6% female, aged 59.4 (2.2) years with BMI of 36.7 and weight 108.1 (5.0) kg.

Why? Short-term diets which replace refined carbohydrates with protein improve cardiovascular risk factors, weight loss and lipid profile. Studies show an inverse relationship between dietary protein and hypertension, and in persons with diabetes high-protein, low-carbohydrate diets have a beneficial effect on postprandial blood glucose and HbA1c.

What (materials)? Continuous Glucose Measuring System (CGMS) to be worn for 48 hours prior to assessments at baseline, 4 months and 12 months, daily food checklist, food frequency questionnaire

What (procedures)? Participants were instructed to consume a high-protein diet.

Who provided? NR. Endocrinologists and own doctors monitored glycaemic control, blood pressure and lipids.

Pedersen 2014 (Continued)

How and where? Face-to-face

When and how much? The intervention duration was 12 months. Further information on contact sessions, their frequency and duration NR. Assessments were done at baseline and at 4-monthly intervals.

Strategies to improve or maintain fidelity; tailoring and modification: Compliance with the protein prescription was monitored by a daily food checklist and a food frequency questionnaire (at baseline, 4 and 12 months) and was also assessed by 24-h urine urea excretion.

Extent of intervention fidelity: Adjusted urea excretion at 12 months was significantly different between groups 519 (39) in high-protein and 456 (25) in standard-protein group; $P = 0.04$). Self-reported diet data confirmed this with a highly significant ($P < 0.01$) difference in change in protein intake between groups.

Concomitant interventions: All but four participants from the total group treated their diabetes with oral blood glucose medication and/or insulin. All were treated with blood pressure medication, and all but two were on statins.

Control diet:

Name (as reported) and brief description: Standard protein diet. Planned protein:fat:carbohydrate ratio was 20:30:50 total energy with a range of protein intake of 55 to 70 g/d. Saturated fat intake was 10% TE; energy limited to 6000 kJ/day.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Participants were 16.7% female, aged 62.4 (1.7) years with BMI of 35.4 and weight 104.7 (3.8) kg.

Why? High-saturated fat and high-protein diets reportedly increase LDL cholesterol, raising some concerns with high-protein low-carbohydrate diets.

What (materials)? Continuous Glucose Measuring System (CGMS) to be worn for 48 hours prior to assessments at baseline, 4 months and 12 months, daily food checklist, food frequency questionnaire

What (procedures)? Participants were instructed to consume a standard-protein diet.

Who provided? NR. Endocrinologists and own doctors monitored glycaemic control, blood pressure and lipids.

How and where? Face-to-face

When and how much? The intervention duration was 12 months. Further information on contact sessions, their frequency and duration NR. Assessments were done at baseline and at 4-monthly intervals.

Strategies to improve or maintain fidelity; tailoring and modification: Compliance with the protein prescription was monitored by a daily food checklist and a food frequency questionnaire (at baseline, 4 and 12 months) and was also assessed by 24-h urine urea excretion.

Extent of intervention fidelity: Adjusted urea excretion at 12 months was significantly different between groups 519 (39) in high-protein and 456 (25) in standard-protein group; $P = 0.04$). Self-reported diet data confirmed this with a highly significant ($P < 0.01$) difference in change in protein intake between groups.

Concomitant interventions: All but four participants from the total group treated their diabetes with oral blood glucose medication and/or insulin. All were treated with blood pressure medication, and all but two were on statins.

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Pedersen 2014 (Continued)

Number of participants with 5% weight loss from baseline at ≥ 12 months: Yes

Change in BMI (kg/m²) at 3 to 12 months: No

Change in BMI (kg/m²) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: Yes

Change in SBP (mmHg) at ≥ 12 months: Yes

All-cause mortality at ≥ 12 months: No

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥ 12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: Yes

Change in LDL (mmol/L) at ≥ 12 months: Yes

Change in HDL (mmol/L) at ≥ 12 months: Yes

Change in non-HDL (mmol/L) at ≥ 12 months: Yes

Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: Yes

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: Yes

Participant-reported adverse effects: No

 Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-glycaemic load diet of 40% carbohydrates, 30% protein and 30% fat. Fibre content was 15g/1000 kcal, daily GI 53 and GL 45g/1000 kcal. Energy restriction of 30% compared with baseline individual energy needs

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: NR

Why? "...individuals with higher insulin secretion lose more weight when randomized to a low-glycemic load diet compared with a high-glycemic load diet."

What (materials)? "During the 6-month intervention period, all food was provided by the research center, and participants were requested to consume only this food and report additional foods if they were eaten."

What (procedures)? "Participants were prescribed a low-glycemic load diet (40% carbohydrate, 30% protein, 30% fat, 15 g fibre/1,000 kcal, mean estimated daily glycemic index of 53, and glycemic load of 45 g/1,000 kcals) at 30% calorie restriction. To maximize adherence to the study diet, regular behavioral group meetings and individual sessions with a dietitian were held. From participants' reports of leftover food and extra items, actual daily nutrient intake during the intervention period was calculated."

Pittas 2005 (Continued)

Who provided? Dietitian

How and where? Group meetings, location NR

When and how much? 24 weeks

Strategies to improve or maintain fidelity; tailoring and modification: Participants were required to only eat food provided and report on any additional food intake. To maximise adherence to the study diet, regular behavioural group meetings and individual sessions with a dietitian were held.

Extent of intervention fidelity: NR

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: High-glycaemic load diet of 60% carbohydrates, 20% protein and 20% fat. Fibre content was 15g/1000 kcal, daily GI 86 and GL 116g/1000 kcal. Energy restriction of 30% compared with baseline individual energy needs

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: NR

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate diet prescribing 25% carbohydrate, 25% protein and 50% fat. Energy prescription of 75% of each participant's resting metabolic rate

Treatment diet type (carbohydrate-fat-protein): Low-high-high

Exercise component? No

Recipients: N = 6 women only with mean (SD) age 41 (6) years, mean (SD) weight 94 (10.9) kg

Why? Increasing carbohydrate when total energy intakes exceed 2.5 MJ/d is proposed to mitigate the adverse effects of a low-energy diet by preventing the decreases in thyroid hormone activity and resting metabolism that are frequently observed.

What (materials)? Participants were given food scales, measuring cups and spoons, and a notebook of meal plans and recipes to assist in their meal preparation.

What (procedures)? The prescribed compositions of the weight reducing low-carbohydrate diet was 25% carbohydrate, 25% protein, 50% fat. The reducing diets were designed to promote a weight loss of 1 kg/wk, with energy levels individually prescribed to approximate 75% of each subject's measured RMR. All participants were required to attend weekly meetings, which included nutrition education classes, group discussions, collection of food diary booklets. Subjects were taught the exchange meal-planning system and were instructed to consume a specific number of exchanges based on their prescribed energy level and diet composition. Subjects recorded all food and beverages they consumed, along with the corresponding exchanges, in daily food diaries. Booklets containing 7 d of daily diaries were collected weekly and analysed by the study dietitian for energy content and distribution by using the exchange system. Each subject received weekly feedback regarding both her dietary compliance and her accuracy in using the exchange system, and the dietitian met individually with subjects as necessary to improve these areas.

Racette 1995 (Continued)

Who provided? Dietitian

How and where? Participants received weekly feedback and met individually with dietitian as required, location NR

When and how much? Weekly meetings which included nutrition education classes, group discussions, collection of food diary booklets and weigh-ins

Strategies to improve or maintain fidelity; tailoring and modification: Subjects recorded all food and beverages they consumed, along with the corresponding exchanges, in daily food diaries. Booklets containing 7 d of daily diaries were collected weekly. Each subject received weekly feedback regarding both her dietary compliance and her accuracy in using the exchange system and the dietitian met individually with subjects as necessary to improve these areas.

Extent of intervention fidelity: NR

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Low-fat diet prescribing 60% carbohydrate, 25% protein and 15% fat. Energy prescription of 75% of each participant's resting metabolic rate

Control diet type (carbohydrate-fat-protein): Balanced-low-high

Exercise component? No

Recipients: N = 7 women only with mean (SD) age 37 (4) years, mean (SD) weight 92.7 (9.0) kg

Why? The maintenance diet was designed to maintain energy balance, with energy levels individually prescribed based on each subject's RMR and an individualised activity factor of 1.6-1.9. RMR values were calculated from the Harris-Benedict formula during MI, whereas the measured RMR values were used during MII. Adjustments were made in the prescribed energy levels as necessary to minimise weight changes. The prescribed composition of the maintenance diet was 45% carbohydrate, 20% protein, and 35% fat.

What (materials)? Participants were given food scales, measuring cups and spoons, and a notebook of meal plans and recipes to assist in their meal preparation.

What (procedures)? The prescribed compositions of the weight-reducing low-fat diet was 60% carbohydrate, 25% protein, 15% fat.  Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-fat low-carbohydrate (HFLC) diet, participants counselled to consume ≤ 40 g/d carbohydrates and 60% of calories as fat ($< 7\%$ calories from saturated fat), and the remaining $\sim 35\%$ from protein. Energy prescription was a 500 kcal deficit from daily caloric needs.

Ruth 2013 (Continued)

Treatment diet type (carbohydrate-fat-protein): Very low-high-high

Exercise component? No

Recipients: Participants were 90% female, aged 43.5 (11.5) years, with BMI 37.1 (4.6) and weight 100.5 (14.8) kg.

Why? High-fat, low-carbohydrate diets have shown beneficial effect on markers of cardiovascular risk as well as improvements in systemic inflammation.

What (materials)? NR

What (procedures)? Participants were instructed to consume a high-fat, low-carbohydrate diet through regular consultations. They were also required to complete food records. A run-in period 1 week before starting the diet. Individual diet counselling biweekly. Daily caloric needs were estimated by the Mifflin-St Jeor equation. All subjects completed take home 3-day food records every two weeks.

Who provided? Study dietitian provided counselling and analysed three-day food records.

How and where? Individual face-to-face meetings with dietitian, Boston Medical Center's General Clinical Research Unit

When and how much? The duration of the intervention was 12 weeks. During this time, participants were counselled by a study dietician on a biweekly basis. Participants had to complete take-home three-day food records (comprising two weekdays and a weekend day) every two weeks.

Strategies to improve or maintain fidelity; tailoring and modification: Completing of food records, regular meetings with dietitian, measurement of weight at the end of the study. Same nurse took all the measurements.

Extent of intervention fidelity: The proportion of participants in the intervention group who lost more than 5% of their body weight was greater than in the control group, which the authors interpreted as greater adherence. Carbohydrate intake was significantly lower in the intervention group when compared to control group ($P < 0.0001$), as was protein and fat ($P < 0.0001$ for both). This group consumed the prescribed amounts of carbohydrate and fat.

Concomitant interventions: No medications were permitted, with participants being asked to stop taking NSAIDs seven days before baseline and follow-up measures.

Control diet:

Name (as reported) and brief description: Low-fat high-carbohydrate (LFHC) diet, participants were counselled to consume ~60% of calories from complex carbohydrates, 25% from fat (< 7% from saturated fat) and 15% from protein. Energy prescription was a 500 kcal deficit from daily caloric needs.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Participants were 88% female, aged 41.5 (12.8) years, with BMI 35.9 (4.8) and weight 99.3 (14.5) kg.

Why? Low-fat, high-carbohydrate diets have shown improvements in systemic inflammation.

What (materials)? NR

What (procedures)? Participants were instructed to consume a low-fat, high-carbohydrate diet through regular consultations. They were also required to complete food records. Individual diet counselling biweekly.

Who provided? Study dietitian provided counselling and analysed three-day food records.

How and where? Individual face-to-face meetings with dietician, Boston Medical Center's General Clinical Research Unit

Ruth 2013 (Continued)

When and how much? The duration of the intervention was 12 weeks. During this time, participants were counselled by a study dietician on a biweekly basis. Participants had to complete take-home three-day food records (comprising two weekdays and a weekend day) every two weeks.

Strategies to improve or maintain fidelity; tailoring and modification: Completing of food records, regular meetings with dietician, measurement of weight at the end of the study. Same nurse took all the measurements.

Extent of intervention fidelity: Carbohydrate intake was somewhat lower than prescribed (56% versus 60%) and protein intake slightly higher (22% versus 15%). Saturated fat intake in this group was higher than was recommended.

Concomitant interventions: No medications were permitted, with participants being asked to stop taking NSAIDs seven days before baseline and follow-up measures.

Outcomes	<p>Change in body weight (kg) at 3 to < 12 months: No</p> <p>Change in body weight (kg) at ≥ 12 months: No</p> <p>Number of participants with 5% weight loss from baseline at 3 to < 12 months: Yes</p> <p>Number of participants with 5% weight loss from baseline at ≥ 12 months: No</p> <p>Change in BMI (kg/m²) at 3 to 12 months: Yes</p> <p>Change in BMI (kg/m²) at ≥ 12 months: No</p> <p>Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No</p> <p>Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No</p> <p>Change in DBP (mmHg) at ≥ 12 months: No</p> <p>Change in SBP (mmHg) at ≥ 12 months: No</p> <p>All-cause mortality at ≥ 12 months: No</p> <p>Cardiovascular mortality at ≥ 12 months: No</p> <p>Non-fatal myocardial infarction at ≥ 12 months: No</p> <p>Non-fatal stroke at ≥ 12 months: No</p> <p>Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No</p> <p>Change in HbA1c (%) at ≥ 12 months: No</p> <p>Change in LDL (mmol/L) at ≥ 12 months: No</p> <p>Change in HDL (mmol/L) at ≥ 12 months: No</p> <p>Change in non-HDL (mmol/L) at ≥ 12 months: No</p> <p>Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: No</p> <p>Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: No</p> <p>Participant-reported adverse effects: No</p>

Study characteristics

Methods

Review comparison(s) addressed by this study: 1

Study design: RCT, parallel, multi-centre (2)

Trial registry number: NCT00072995

Total number of trial arms: 4

Year trial started: 2004

Sample size calculation: Yes

Outcome(s) used for sample size calculation: Weight loss

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 2 years

What was the duration of the weight maintenance phase: NA

Other notes about methods: NA

Participants

Country and setting: USA, outpatient university hospital in Boston and outpatient biomedical research centre in Baton Rouge

Eligibility criteria: Participants aged between 30 and 70 years with a BMI between 25 and 40 kg/m². Participants were excluded if they had diabetes or unstable cardiovascular conditions; used medication which affected weight or had insufficient motivation as judged by questionnaire.

Type 2 diabetes at baseline: No

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Mixed

Total number randomised: 811

Total attrition in trial: 166

Treatment diet

Participants randomised: 201

Participants withdrawn (voluntary): 6

Total attrition: 33

Control diet:

Sacks 2009 (Continued)

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-fat high-protein, 40% fat, 25% protein and 35% carbohydrates; 90 min of moderate physical exercise. Each participant's caloric prescription represented a deficit of 750 kcal per day from baseline resting energy expenditure.

Treatment diet type (carbohydrate-fat-protein): Low-high-high

Exercise component? Yes

Recipients: Participants were 64% female, aged 51 (9) years, with BMI 33(4) and weight 94 (16) kg. A total of 29% of participants had a BMI between 25 and 29.9; 71% had a BMI \geq 30, and 40% were hypertensive.

Why? To determine the effects of a high-fat high-protein diet, together with regular exercise, on long-term weight loss (2 years). To facilitate a dose-response test of carbohydrate content

What (materials)? Structured meal plans, food diaries, food shopping lists and easy-to-prepare recipes, based on the American Dietetic Association (ADA) exchange system (booklet)

What (procedures)? Participants were instructed to consume a high-fat, high-protein diet with regular group and individual sessions over the course of the intervention. Participants were asked to maintain food and beverage diaries and self-monitor their intake goals. Group sessions consisted of nutrition education, behavioural methods and social support. Each participant's caloric prescription represented a deficit of 750 kcal per day from baseline, as calculated from the person's resting energy expenditure and activity level. Structured meal plans were provided based on the American Dietetic Association (ADA) exchange system. The goal for physical activity was 90 minutes of moderate exercise per week.

Who provided? Behavioural counsellors, registered dietitians and 'other study staff members'.

How and where? Face-to-face group and individual sessions attended regularly, location NR. Web-based self-monitoring was completed by participants.

When and how much? The duration of the intervention was two years. During the first six months, group sessions lasting one hour were provided three out of every four weeks; and thereafter two out of every four weeks for the remainder of the intervention. Individual sessions with dietitians, lasting 30 minutes each, were scheduled every eight weeks for the duration of the intervention. Food and beverage diaries and web-based self-monitoring of food intake was done daily.

Strategies to improve or maintain fidelity; tailoring and modification: Participants were instructed to record their food and beverage intake in a daily food diary and in a Web based self-monitoring tool that provided information on how closely their daily food intake met the goals for macronutrients and energy. Behavioural counselling was integrated into the group and individual sessions to promote adherence to the assigned diets (e.g. behavioural strategies such as goal-setting, problem-solving). Self-monitoring indicated how well food intake corresponded with the prescribed macronutrient and energy intakes, regular weight monitoring; team members praised participants for success. Dietary intake of participants was assessed by 24-hour recalls at 6 months and 2 years (three telephone interviews within a 3-week period, 2 weekdays and a weekend day) in a 50% random sample selected. Participation in exercise was monitored by questionnaire (at 12 and 24 months follow-up) and by the online self-monitoring tool.

Extent of intervention fidelity: Attendance at individual counselling was higher than for group counselling (64.3 versus 53.8% overall, 69.5 versus 55.3% in intervention arm). Adherence data from subsample (n = 177): % Individual sessions attended, means (SD): 69.5 (30.7); % group sessions attended, means (SD): 55.3 (20.0); % of days with completed food entries, means (SD): 60.1 (31.9); % of days with physical activity entries, means (SD): 29.8 (22.4); % discrepancy (kcal goal), means (SD): -9.5 (11.4); % discrepancy (protein goal), means (SD): -14.5 (13.2); % discrepancy (fat goal), means (SD): -13.8 (14.8); % discrepancy (carbohydrate goal), means (SD): -1.4 (13.2)

Sacks 2009 (Continued)

Concomitant interventions: Use of medicines at baseline: Antihypertensive medication, n/N (%) : 61/201 (30%); lipid-lowering medication, n/N (%) : 31/201 (15%)

Control diet:

Name (as reported) and brief description: Low-fat average-protein, 20% fat, 15% protein and 65% carbohydrates; 90 min of moderate physical exercise. Each participant's caloric prescription represented a deficit of 750 kcal per day from baseline resting energy expenditure.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: Participants were 62% female, aged 51 (9) years, with BMI 33(4) and weight 94 (16) kg. A total of 25% of participants had a BMI between 25 and 29.9; 75% had a BMI \geq 30, and 34% were hypertensive.

Why? Studies which followed up participants on different diets found that low-carbohydrate, high-protein were not superior to high-carbohydrate, low-fat diets.

What (materials)? Structured meal plans, food diaries, food shopping lists and easy-to-prepare recipes, based on the American Dietetic Association (ADA) exchange system (booklet)

What (procedures)? Participants were instructed to consume a low-fat, average-protein diet with regular group and individual sessions over the course of the intervention. Participants were asked to maintain food and beverage diaries and self-monitor their intake goals. Group sessions consisted of nutrition education, behavioural methods and social support [from 72 Williamson 2010]. The goal for physical activity was 90 minutes of moderate exercise per week.

Who provided? Behavioural counsellors, registered dietitians and 'other study staff members'.

How and where? Face-to-face group and individual sessions attended regularly, location NR. Web-based self-monitoring was completed by participants.

When and how much? The duration of the intervention was two years. During the first six months, group sessions lasting one hour were provided three out of every four weeks; and thereafter two out of every four weeks for the remainder of the intervention. Individual sessions with dietitians, lasting 30 minutes each, were scheduled every eight weeks for the duration of the intervention. Food and beverage diaries and web-based self-monitoring of food intake was done daily.

Strategies to improve or maintain fidelity; tailoring and modification: Participants were instructed to record their food and beverage intake in a daily food diary and in a Web-based self-monitoring tool that provided information on how closely their daily food intake met the goals for macronutrients and energy. Behavioural counselling was integrated into the group and individual sessions to promote adherence to the assigned diets (e.g. behavioural strategies such as goal-setting, problem-solving). Self-monitoring indicated how well food intake corresponded with the prescribed macronutrient and energy intakes, regular weight monitoring; team members praised participants for success. Dietary intake of participants was assessed by 24-hour recalls at 6 months and 2 years (three telephone interviews within a 3-week period, 2 weekdays and a weekend day) in a 50% random sample selected. Participation in exercise was monitored by questionnaire (at 12 and 24 months follow-up) and by the online self-monitoring tool.

Extent of intervention fidelity: Attendance at individual counselling was higher than for group counselling (64.3 versus 53.8% overall, 61.6 versus 55.2% in intervention arm). Adherence data from subsample (n = 170): % Individual sessions attended, means (SD): 61.6 (31.2); % group sessions attended, means (SD): 55.2 (21.8); % of days with completed food entries, means (SD): 56.7 (34.2); % of days with physical activity entries, means (SD): 27.9 (23.1); % discrepancy (kcal goal), means (SD): -13.3 (13.1); % discrepancy (protein goal), means (SD): -3.1 (14.9); % discrepancy (fat goal), means (SD): 0.4 (26.3); % discrepancy (carbohydrate goal), means (SD): -19.9 (14.5)

Concomitant interventions: Use of medicines at baseline: Antihypertensive medication, n/N (%) : 54/204 (26%); lipid-lowering medication, n/N (%) : 32/204 (16%)

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

264

Sacks 2009 (Continued)

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: Yes

Change in BMI (kg/m²) at 3 to 12 months: No

Change in BMI (kg/m²) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: Yes

Other notes about participants: HbA1c and blood lipid baseline equivalence NR; could not assess statistical significance

 Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate ad libitum diet, subjects were instructed to restrict carbohydrates to 30 g per day or less. No instructions on reducing total fat intake were provided. Vegetables and fruits with high ratios of fibre to carbohydrates were recommended.

Samaha 2003 (Continued)

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? No

Recipients: Subjects were 20% female and aged mean (SD) 53 (9) years, with BMI mean (SD) 42.9 (6.6) and weight 130.0 (22.7) kg. Forty-one percent had diabetes mellitus, 45% had metabolic syndrome without diabetes, 72% had hypertension, 51% had hyperlipidemia and 16% had coronary artery disease.

Why? Severely obese subjects with a high prevalence of diabetes or the metabolic syndrome would have a greater weight loss, without detrimental effects on risk factors for atherosclerosis, while on a low-carbohydrate diets. There are concerns that carbohydrate restriction might have adverse effects on serum lipids. The intervention was administered to determine weight loss and changes in cardiovascular risk factors resulting from a low-carbohydrate diet.

What (materials)? Diet overview handout, instructional nutrition labels, sample menus and recipes, and a book on counting calories and carbohydrates. No specific exercise programme was recommended

What (procedures)? Participants were prescribed carbohydrate restriction of 30 g or less per day. They received two hours of group-teaching sessions each week for four weeks, thereafter one hour per month for five additional months. All sessions were led by an expert in nutritional counselling.

Who provided? Experts in nutritional counselling

How and where? Face-to-face group sessions, location NR

When and how much? Four weekly sessions of two hours each, followed by five monthly sessions of one hour; over the course of six months

Strategies to improve or maintain fidelity; tailoring and modification: Sessions were held in groups, weighing and waist measurement at six months and determination of dietary compliance using a validated instrument for 24-hour recall of consumption

Extent of intervention fidelity: Subjects decreased their caloric intake from 2153 (1060) to 1343 (731) kcal ($P < 0.001$). These subjects also significantly increased their intake of fat to 44 (16)% and protein to 25 (10)%, and decreased their carbohydrate intake to 31 (19)%.

Concomitant interventions: Of intervention participants; 11% were treated with sulfonylurea, 17% with metformin, 2% with peroxisome proliferator-activated receptor gamma antagonist and 9% with insulin. Sixty-four percent received antihypertensive therapy, 42% received statins and 3% received gemfibrozil.

Control diet:

Name (as reported) and brief description: Low-fat diet, subjects were instructed to follow diet according to the obesity-management guidelines of the National Heart, Lung and Blood Institute, including caloric restriction sufficient to create a deficit of 500 calories per day, with 30% or less of total calories from fat. From the guideline: 55% or more of total calories; protein approximately 15% of total calories and 30% or less of total fat.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Subjects were 15% female and aged mean (SD) 54 (9) years, with BMI mean (SD) 42.9 (7.7) and weight 131.8 (27.3) kg. Thirty-eight percent had diabetes mellitus, 41% had the metabolic syndrome without diabetes, 57% had hypertension, 50% had hyperlipidemia and 16% had coronary artery disease.

Why? NR

What (materials)? Diet overview handouts, instructional nutritional labels, sample menus and recipes as well as a book on how to count calories and carbohydrates ([National Heart, Lung, and Blood Institute 1998](#)).

Samaha 2003 (Continued)

What (procedures)? Participants were prescribed a low-fat diet. They received two hours of group-teaching sessions each week for four weeks, thereafter one hour per month for five additional months. All sessions were led by an expert in nutritional counselling.

Who provided? Experts in nutritional counselling

How and where? Face-to-face group sessions, location NR

When and how much? Four weekly sessions of two hours each, followed by five monthly sessions of one hour; over the course of six months

Strategies to improve or maintain fidelity; tailoring and modification: Sessions were held in groups, weighing and waist measurement at six months and determination of dietary compliance using a validated instrument for 24-hour recall of consumption

Extent of intervention fidelity: [From 25 Seshadri 2005] Subjects decreased their caloric intake from 1882 (820) to 1590 (679) kcal ($P = 0.057$). There was no significant change in macronutrient intake, with intake at 16 (5)% for protein, 51 (15)% for carbohydrate and 32 (15)% for fat at six months.

Concomitant interventions: Of control participants; 16% were treated with sulfonylurea, 13% with metformin, 2% with peroxisome proliferator-activated receptor gamma antagonist and 4% with insulin. Fifty-seven percent received antihypertensive therapy, 37% received statins and 2% received niacin.

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes, in participants with type 2 diabetes mellitus

Change in body weight (kg) at ≥ 12 months: No

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m^2) at 3 to 12 months: No

Change in BMI (kg/m^2) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: No

Change in SBP (mmHg) at ≥ 12 months: No

All-cause mortality at ≥ 12 months: No

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥ 12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: No

Change in LDL (mmol/L) at ≥ 12 months: No

Change in HDL (mmol/L) at ≥ 12 months: No

Change in non-HDL (mmol/L) at ≥ 12 months: No

Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: No

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: No

Samaha 2003 (Continued)

Participant-reported adverse effects: No

Notes

Participants

Country and setting: USA, outpatient centre for integrative medicine in San Francisco

Eligibility criteria: Participants 18 years or older with BMI ≥ 25 kg/m² and HbA1c > 6.0%. Participants were excluded if they were currently using insulin or were taking more than three glucose-lowering agents.

Type 2 diabetes at baseline: Mixed; stratified with T2DM since participant eligibility criteria were diabetes or prediabetes (HbA1c ≥ 6.5 or > 6%, respectively), and at baseline 75% of treatment & 72% of control group were on diabetes medication.

Impaired glucose tolerance at baseline: Mixed

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Mixed

Total number randomised: 34

Total attrition in trial: 5

Treatment diet
Participants randomised: 16

Participants withdrawn (voluntary): NR

Total attrition: 2

Saslow 2017a (Continued)

Other notes about participants: Participant flow in supplementary files is different to that reported in Saslow et al 2014. Baseline characteristics are estimated marginal means.

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate ketogenic (LCK) ad libitum diet, very low carbohydrate, high-fat, non calorie-restricted diet reducing carbohydrate intake to 20-50 grams per day. Participants were instructed to eat a normal amount of protein and derive their remaining calories from fat.

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? No

Recipients: Diabetics or prediabetics, 56.3% female, aged mean (SD) 64.8 (7.7) years with 69% having a BMI above 30. A total of 81% had dyslipidemia and 63% had hypertension.

Why? Uncertainty exists around the optimal diet for managing diabetics and prediabetics. Some research indicates that ad libitum low-carbohydrate ketogenic diets may improve metabolic measures of these patients, and reduce the need for medication.

What (materials)? "Abbott Precision Xtra Monitoring System and blood ketone test strips. Home glucose meter for participants on diabetes medication other than metformin. Audio CDs for meditation."

What (procedures)? Participants attended twelve weekly classes followed by three classes every two weeks and four classes every two months related to eating a low-carbohydrate ketogenic diet, which was presented by an author in the manuscript. On week 6 of the intervention participants were taught the importance of sleep and exercise while a third group leader instructed participants on increasing positive affect and mindfulness as well as meditation. To develop mindful eating skills, participants were asked to practice a guided meditation 10 minutes per day at least three times a week using audio CDs recorded for the intervention, and to use several mindful eating practices during meal times, such as focussing awareness on the taste and texture of foods while eating. Blood glucose was monitored in patients on diabetes medications, except metformin.

Who provided? The group leader responsible for teaching classes was an author of the manuscript and had experience in the low-carbohydrate dietary approach. Qualification of group leader providing information on supportive behavioural strategies NR

How and where? Format and location of meetings NR. Ketosis and blood glucose were measured at home by participants.

When and how much? Twelve weekly classes were for two hours, three classes every two weeks for two hours and four classes every two months were 1.5 hours over the course of the 12-month intervention. Meditation for 10 minutes per day at least three days a week was encouraged. Ketosis was tested for twice a week and glucose monitoring done in the morning before breakfast and just before dinner.

Strategies to improve or maintain fidelity; tailoring and modification: Teaching positive affect and mindfulness, meditation, recording of food using Automated Self-Administered 24-h Dietary Recall (ASA24), measurement of weight during visits

Extent of intervention fidelity: Authors only reported 'fair' adherence rates.

Concomitant interventions: Around 31% participants used metformin alone, 44% used metformin combination therapy, behavioural adherence strategies to increase positive affect and mindfulness.

Control diet:

Name (as reported) and brief description: Moderate-carbohydrate, calorie-restricted (MCCR) diet, consistent with guidelines from ADA, where participants were encouraged to derive 45 to 50% of calories from carbohydrates through counting carbohydrates in 15 g units, and eating 500 fewer kilocalories (kcal) per day than their calculated maintenance needs.

Saslow 2017a (Continued)

Control diet type (carbohydrate-fat-protein): Balanced-unclear-unclear

Exercise component? No

Recipients: Diabetics or prediabetics, 88.9% female, aged mean (SD) 55.1 (13.5) years with 83% having a BMI above 30. A total of 56% had dyslipidemia and 78% had hypertension.

Why? Uncertainty exists around the optimal diet for managing diabetics and prediabetics.

What (materials)? "American Diabetes Association guidelines (ADA 2009; Inzucchi 2012). Audio CDs for meditation."

What (procedures)? Participants attended twelve weekly classes followed by three classes every two weeks and four classes every two months related to eating a moderate-carbohydrate calorie-restricted diet, which was presented by a registered dietitian. In week 6 of the intervention participants were taught the importance of sleep and exercise while a third group leader instructed participants on increasing positive affect and mindfulness as well as meditation. Topics were drawn from two prior behavioural intervention models for diet and health behaviour change. To develop mindful eating skills, participants were asked to practice a guided meditation 10 minutes per day at least three times a week using audio CDs recorded for the intervention, and to use several mindful eating practices during meal times, such as focussing awareness on the taste and texture of foods while eating. Blood glucose was monitored in patients on diabetes medications, except metformin. Physical symptoms and activity was also assessed.

Who provided? The group leader responsible for teaching classes is a registered dietitian with several years of diabetes education experience. Qualification of group leader providing information on supportive behavioural strategies NR

How and where? Format and location of meetings NR

When and how much? Twelve weekly classes were for two hours, three classes every two weeks for two hours and four classes every two months were 1.5 hours over the course of the 12 month intervention. Meditation for 10 minutes per day at least three days a week was encouraged.

Strategies to improve or maintain fidelity; tailoring and modification: Teaching positive affect and mindfulness, meditation, recording of food using Automated Self-Administered 24-h Dietary Recall (ASA24), measurement of weight during visits

Extent of intervention fidelity: Authors only reported 'fair' adherence rates.

Concomitant interventions: Around 31% participants used metformin alone, 44% used metformin combination therapy, behavioural adherence strategies to increase positive affect and mindfulness.

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: Yes

Change in BMI (kg/m²) at ≥ 12 months: Yes

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: Yes

Change in SBP (mmHg) at ≥ 12 months: Yes

All-cause mortality at ≥ 12 months: No

Saslow 2017a (Continued)

Cardiovascular mortality at ≥ 12 months: No
Non-fatal myocardial infarction at ≥ 12 months: No
Non-fatal stroke at ≥ 12 months: No
Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No
Change in HbA1c (%) at ≥ 12 months: Yes
Change in LDL (mmol/L) at ≥ 12 months: Yes
Change in HDL (mmol/L) at ≥ 12 months: Yes
Change in non-HDL (mmol/L) at ≥ 12 months: No
Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: No
Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: Yes
Participant-reported adverse effects: Yes

Total number of trial arms: 2
Year trial started: 2013
Sample size calculation: Yes
Outcome(s) used for sample size calculation: Change in HbA1c
Duration of run-in period (weeks): NA
What was the duration of the weight loss phase: 6 months
What was the duration of the weight maintenance phase: 12 months
Other notes about methods: NA

Participants

Country and setting: Japan, outpatient clinic of a university hospital in Tokyo

Sato 2017 (Continued)

Eligibility criteria: Participants with type 2 diabetes; aged between 20 and 75 years with HbA1c above 7.5% and fluctuations within $\pm 0.5\%$ for the past three months, who had a BMI more than 23 kg/m² and had received two or more educational programmes on caloric restriction. Participants were excluded if they had been diagnosed with proliferative or severe retinopathy; serious kidney disease with specified range of serum creatinine (with or without microalbuminuria); serious liver disease with specified ranges of aspartate and alanine aminotransferase levels; acute heart failure in the past three months or chronic heart failure; active malignancies; serious pancreatic or infectious disease; were pregnant; suffered a traumatic injury; were alcohol dependent or ate less than 130 g carbohydrates per day.

Type 2 diabetes at baseline: Yes

Impaired glucose tolerance at baseline: No

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Mixed

Total number randomised: 66

Total attrition in trial: 17

Treatment diet

Participants randomised: 33

Total attrition: 11

Control diet:

Participants randomised: 33

Participants withdrawn (voluntary): 5

Total attrition: 6

Baseline data treatment diet:

Randomised participants not included: 3/33

Age (years): mean (SD) 60.5 (10.5)

Gender distribution (as reported): female 7/30, male 23/30

Weight (kg): median (IQR) 74.0 (66.2 to 86.4)

BMI (kg/m²): median (IQR) 26.7 (25.0 to 30.0)

DBP (mmHg): NR

SBP (mmHg): NR

HbA1c (%): median (IQR) 8.0 (7.6 to 8.9)

LDL (mmol/L): median (IQR) 2.63 (2.19 to 3.03)

HDL (mmol/L): median (IQR) 1.13 (1.01 to 1.36)

Non-HDL (mmol/L): NR

TC (mmol/L): NR

TG (mmol/L): median (IQR) 1.62 (1.16 to 2.68)

Baseline data control diet:

Sato 2017 (Continued)

Randomised participants not included: 1/33

Age (years): mean (SD) 58.4 (10.0)

Gender distribution (as reported): female 8/32, male 24/32

Weight (kg): median (IQR) 73.6 (68.1 to 88.0)

BMI (kg/m²): median (IQR) 26.5 (24.6 to 30.1)

DBP (mmHg): NR

SBP (mmHg): NR

HbA1c (%): median IQR 8.3 (8.0 to 9.3)

LDL (mmol/L): median (IQR) 2.51 (2.25 to 3.34)

HDL (mmol/L): median (IQR) 1.22 (0.99 to 1.39)

Non-HDL (mmol/L): NR

TC (mmol/L): NR

TG (mmol/L): median (IQR) 1.68 (1.01 to 2.27)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Participants were Japanese and BMI cut-offs are lower for this population.

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate diet (LCD) consumed ad libitum, set target carbohydrate intake at 130 g/d with participants asked to consume equal amounts of carbohydrates per meal (43.3 g). No other restrictions were given with the exception of recommending the intake of unsaturated rather than saturated fat.

Treatment diet type (carbohydrate-fat-protein): Low-unclear-unclear

Exercise component? No

Recipients: Participants were type 2 diabetics, 23.3% female and aged 60.5 (10.5) years, with median BMI 26.7 (IQR 25.0 to 30.0) and median weight 74.0 (IQR 66.2 to 86.4) with the disease for an average of 15.5 years.

Why? Many patients with type 2 diabetes struggle to adhere to calorie-restricted diets. In the United States and Europe there is much debate about the use of low-carbohydrate diets in the treatment of type 2 diabetes. LCD in patients with uncontrolled T2DM is preferable for HbA1c and weight reduction.

What (materials)? Recommendation as per [Accurso 2008](#). Other written materials prepared by study physicians and dietitians, containing key points on nutrition therapy and food lists.

What (procedures)? Participants were assigned to the low-carbohydrate diet (< 130 g/day), with target carbohydrate contents per meal and preferential use of unsaturated over saturated fat prescribed.

Who provided? Study physicians explained the protocol and supported with the preparation of written materials. Dietitians led regular patients meetings. Attending outpatient physicians were allowed to make changes to medications at each study visit. Participants kept three-day weighed/measured food records. Physicians followed up during the weight maintenance phase.

Sato 2017 (Continued)

How and where? Individual face-to-face meetings at an outpatient clinic of Juntendo University Hospital

When and how much? The intervention duration comprised six months of active weight loss and a 12-month weight maintenance phase. The initial visit was a detailed explanation of the protocol by study physicians, followed by 30-minute-long nutrition meetings with dietitians at one, two, four and six months in the active weight-loss phase; one meeting in the weight maintenance phase at 18 months. As part of these meetings, participant-recorded three-day weighed/measured food records were used to analyse food intake. In the weight maintenance phase, participants were followed up by physicians approximately every two months.

Strategies to improve or maintain fidelity; tailoring and modification: Three-day weighed/measured food records for each visit with dietitian, completion of compliance questionnaire at the end of the study, weigh-ins at study visits

Extent of intervention fidelity: The authors reported that more participants withdrew from the low-carbohydrate group and interpreted this as difficulty with adherence. They did, however, report that adherence was good. Carbohydrate intake from baseline to six months decreased from 223.2 (52.4) to 148.8 (31.3) g/day.

Concomitant interventions: Four participants (13.3%) were on basal supported oral therapy, and 23.3% on intensive insulin therapy (basal insulin at 17 (11) units/day and bolus insulin at 16 (18) units/day). A total of 36.7% were on metformin, 63.3% on thiazolidine, 13.3% on dipeptidyl peptidase-4 inhibitor, 53.3% on alpha-glucosidase inhibitor and 23.3% on glinide. Two participants (6.7%) were on GLP-1 receptor antagonist. Furthermore, 36.7% were on antihypertensive agents, 66.7% were on lipid-lowering agents and 33.3% were on other medications.

Control diet:

Name (as reported) and brief description: Calorie-restricted diet (CRD), target carbohydrate content of 50 to 60% TE and 1.0 to 1.2 g protein per kg body weight, with the balance of calories from fat. Total calorie intake was calculated by multiplication of the ideal body weight by 28 kcal/kg.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Participants were type 2 diabetics, 25.0% female and aged 58.4 (10.0) years, with median BMI 26.5 (IQR 24.6 to 30.1) and median weight 73.6 (IQR 68.1 to 88.0) with the disease for an average of 13 years.

Why? To assess whether calorie-restricted diet was better than LCD for weight loss

What (materials)? Recommendations of the Japan Diabetes Society ([The Japan Diabetes Society 2016](#)). Other written materials prepared by study physicians and dietitians, containing key points on nutrition therapy and food lists

What (procedures)? Participants were assigned to caloric restriction.

Who provided? Study physicians explained the protocol and supported with the preparation of written materials. Dietitians led patient regular patients meetings. Attending outpatient physicians were allowed to make changes to medications at each study visit. Participants kept three-day weighed/measured food records. Physicians followed up during the weight maintenance phase.

How and where? Individual face-to-face meetings at an outpatient clinic of Juntendo University Hospital

When and how much? The intervention duration comprised six months of active weight loss and a 12-month weight maintenance phase. The initial visit was a detailed explanation of the protocol by study physicians, followed by 30-minute-long nutrition meetings with dietitians at one, two, four and six months in the active weight-loss phase; one meeting in the weight maintenance phase at 18 months. As part of these meetings, participant-recorded three-day weighed/measured food records were used to analyse food intake. In the weight maintenance phase, participants were followed up by physicians approximately every two months.

Sato 2017 (Continued)

Strategies to improve or maintain fidelity; tailoring and modification: Three-day weighed/measured food records for each visit with dietitian, completion of compliance questionnaire at the end of the study, weigh-ins at study visits

Extent of intervention fidelity: The authors reported that adherence was good. Carbohydrate intake from baseline to six months changed from 214.4 (51.1) to 203.9 (56.7) g/day.

Concomitant interventions: One participant (3.1%) was on basal supported oral therapy, and 40.6% on intensive insulin therapy (basal insulin at 16 (7) units/day and bolus insulin at 22 (9) units/day). A total of 43.8% were on metformin, 65.6% on thiazolidine, 15.6% on dipeptidyl peptidase-4 inhibitor, 56.3% on alpha-glucosidase inhibitor and 9.4% on glinide. One participant (3.1%) was on GLP-1 receptor antagonist. Furthermore, 40.6% were on antihypertensive agents, 68.8% were on lipid-lowering agents and 31.3% were on other medications.

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: Yes

Change in BMI (kg/m²) at ≥ 12 months: Yes

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: No

Change in SBP (mmHg) at ≥ 12 months: No

All-cause mortality at ≥ 12 months: No

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥ 12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: Yes

Change in LDL (mmol/L) at ≥ 12 months: Yes

Change in HDL (mmol/L) at ≥ 12 months: Yes

Change in non-HDL (mmol/L) at ≥ 12 months: No

Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: No

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: Yes

Participant-reported adverse effects: No

Participants

Country and setting: USA, outpatient clinical research centre at a university in Knoxville. All food required to complete the respective diets was provided, predominantly as frozen foods.

Eligibility criteria: Participants were aged 20 to 50 years with a BMI 30 to 55 kg/m² and pre-diabetes; with fasting glucose < 126 mg/dL, 2-hour oral glucose tolerance test level of 140 to 199 mg/dL and HbA1c of 5.7 to 6.4%. Participants were excluded if they had proteinuria or serum creatinine above 1.5 mg/dL; surgically-induced or premature menopause; history of liver disease, abnormal liver function or diabetes; were on antidiabetic medication or insulin; had thyroid disease with abnormal thyroid-stimulating hormone levels; weighed more than 350 pounds; had triglyceride level > 400 mg/dL, LDL cholesterol > 160 mg/dL, systolic blood pressure > 145 or diastolic blood pressure > 100 mmHg; used medication known to affect the metabolism of lipids or glucose; were pregnant or wanting to become pregnant in the next six months; had weight loss of more than 5% of body weight in the past six months; smoked or had a history of cancer which was actively treated.

Type 2 diabetes at baseline: No

Impaired glucose tolerance at baseline: Yes

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Mixed

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High-protein low-carbohydrate (HP) diet, 40% carbohydrates, 30% fat and 30% protein. Energy reduced to 500 kcal/day less than caloric need. Caloric needs were established for each individual and 500 kcal/day were subtracted from the determined caloric needs for maintenance.

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: Sedentary adults (female 75%; male 25%) with a mean age of 43.1 (1.3) years, with a mean BMI of 40.5 (1.8) kg/m², and with pre-diabetes (fasting glucose of <126 mg/dL, 2-hour glucose level of 140–199 mg/dL during a standard oral glucose tolerance test (OGTT), and glycated haemoglobin (HbA1c) of 5.7–6.4%)

Why? A hypocaloric high-protein diet may result in greater satiety and reduced energy intake, compared to high-carbohydrate diet. It may also help preserve B-cell function by increasing insulin sensitivity and thus decreasing the insulin load per meal. Therefore, such a diet may result in the remission of pre-diabetes to normal glucose tolerance, in obese participants.

What (materials)? Daily food menus - three meals a day plus snacks between meals; provision of prepackaged frozen food (available at local grocery stores) for the duration of the study

What (procedures)? Participants were asked to keep a food diary for a week. Those found to be non-adherent and unable to keep diet diary or deemed unable to adhere to the protocol were excluded. Calorie maintenance needs were determined on an individual basis using the RMR (indirect calorimetry). After maintenance, caloric needs were established for each individual; 500 kcals/day were subtracted from the determined caloric needs to promote a 1–2 lbs weekly weight loss. Dietary fat sources (30% of total energy) in the diet focused on monounsaturated and polyunsaturated fats, i.e. plant oils, semi-liquid margarine, and nuts; dietary carbohydrate sources (40% of total energy) emphasised whole grains, fruits, vegetables, and legumes; and dietary protein sources (30% of total energy) included lean meats, fish chicken, eggs, and nonfat dairy foods, i.e. fat-free milk and low-fat cheese, consistent with American Diabetes Association and Institute of Medicine guidelines. The diet met the recommended daily intake for minerals and vitamins for women aged 20 to 50 years.

Who provided? Dietitian

How and where? Face-to-face consultations at the General Clinical Research Centre, University of Tennessee; phone and email consultation provided when needed

When and how much? Every week for 24 weeks. A one-time calorie reduction of 200 kcal was made if a participant reached a plateau and did not lose weight for two consecutive weeks during the 6 months.

Strategies to improve or maintain fidelity; tailoring and modification: Dietary compliance assessed by both subjective and objective parameters (not described in detail). Strategies to increase compliance included frequent interaction, behaviour modification, individualised diet with food variety and

Stentz 2016 (Continued)

food record system. The meals were dispensed as prepackaged foods from stored frozen food by the dietitian affiliated with the UT GCRC dietary services on the site of the GCRC, maintaining the macronutrient and caloric requirements established at randomisation. The food records served as a motivational enforcement compliance.

Extent of intervention fidelity: % compliance reported: 93 (1.6).

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: High-carbohydrate low-protein (HC) diet, 55% carbohydrates, 30% fat and 15% protein. Energy reduced to 500 kcal/day less than caloric need. Caloric needs were established for each individual and 500 kcal/day were subtracted from the determined caloric needs for maintenance.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Adults (female 83%; male 17%) with a mean age of 41.1 (1.7) years, with a mean BMI of 37.4 (1.7) kg/m², and with pre-diabetes (fasting glucose of < 126 mg/dL, 2-hour glucose level of 140–199 mg/dL during a standard oral glucose tolerance test (OGTT), and glycated haemoglobin (HbA1c) of 5.7–6.4%)

Why? A hypocaloric high-carbohydrate diet may not result in greater satiety and reduced energy intake, compared to a high-protein diet. It may not help preserve B-cell function by increasing insulin sensitivity and thus decreasing the insulin load per meal. Therefore, such a diet may not result in the remission of pre-diabetes to normal glucose tolerance, in obese participants.

What (materials)? Daily food menus - three meals a day plus snacks between meals; provision of prepackaged frozen food (available at local grocery stores) for the duration of the study

What (procedures)? Participants were asked to keep a food diary for a week. Those found to be non-adherent and unable to keep diet diary or deemed unable to adhere to the protocol were excluded. Calorie maintenance needs were determined on an individual basis using the RMR (indirect calorimetry). After maintenance, caloric needs were established for each individual; 500 kcals/day were subtracted from the determined caloric needs to promote a 1–2 lbs weekly weight loss. Dietary fat sources (30% of total energy) in the diet focussed on monounsaturated and polyunsaturated fats, i.e. plant oils, semi-liquid margarine, and nuts; dietary carbohydrate sources (55% of total energy) emphasised whole grains, fruits, vegetables, and legumes; and dietary protein sources (15% of total energy) included lean meats, fish chicken, eggs, and nonfat dairy foods, i.e. fat-free milk and low-fat cheese, consistent with American Diabetes Association and Institute of Medicine guidelines. The diet met the recommended daily intake for minerals and vitamins for women aged 20 to 50 years.

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

283

Tay 2008 (Continued)

Trial registry number: ACTRN12606000203550

Total number of trial arms: 2

Year trial started: 2006

Sample size calculation: No

Outcome(s) used for sample size calculation: NA

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 52 weeks

What was the duration of the weight maintenance phase: NA

Other notes about methods: NA

Participants

Country and setting: NR; likely Australia based on authors and funders

Eligibility criteria: Participants aged 18 to 65 years with abdominal obesity and the presence of at least one additional risk factor for metabolic syndrome. Participants were excluded if they had a history of liver, cardiovascular, peripheral vascular, respiratory or gastrointestinal diseases; diabetes; or malignancy.

Type 2 diabetes at baseline: No

Impaired glucose tolerance at baseline: Mixed

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Mixed

Total number randomised: 118

Total attrition in trial: 30

Treatment diet

Participants randomised: 57

Participants withdrawn (voluntary): 12

Total attrition: 12

Control diet:

Participants randomised: 61

Participants withdrawn (voluntary): 18

Total attrition: 18

Baseline data treatment diet:

Randomised participants not included: 12/57

Age (years): mean (SD) 50.3 (8.4)

Gender distribution (as reported): female 31/45 (68.9%), male 14/45 (31.1%)

Weight (kg): mean (SD) 94.4 (15.5)

BMI (kg/m²): mean (SD) 33.9 (4.3)

DBP (mmHg): mean (SD) 73.6 (11.6)

Tay 2008 (Continued)

SBP (mmHg): mean (SD) 133.5 (14.5)

HbA1c (%): NR

LDL (mmol/L): mean (SD) 3.2 (0.9)

HDL (mmol/L): mean (SD) 1.4 (0.3)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.4 (0.9)

TG (mmol/L): mean (SD) 1.6 (0.7)

Baseline data control diet:

Randomised participants not included: 18/61

Age (years): mean (SD) 51.0 (7.5)

Gender distribution (as reported): female 26/43 n/N (60.5%), male 17/43 n/N (39.5%)

Weight (kg): mean (SD) 95.2 (12.6)

BMI (kg/m²): mean (SD) 33.5 (4.1)

DBP (mmHg): mean (SD) 77.8 (10.1)

SBP (mmHg): mean (SD) 136.1 (12.6)

HbA1c (%): NR

LDL (mmol/L): mean (SD) 3.3 (0.7)

HDL (mmol/L): mean (SD) 1.3 (0.4)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.4 (0.8)

TG (mmol/L): mean (SD) 1.8 (0.8)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Very-low-carbohydrate high-fat (VLCHF) diet. 4% of total energy as carbohydrate, 35% protein and 61% total fat (20% saturated). Carbohydrate intake was restricted to < 20 g/day during the first 8 weeks of the study whereafter subjects were given the option to increase to < 40 g/day for the remaining 16 weeks. Moderate energy restriction of 30% (prescription of 6000 kJ for women and 7000 kJ for men).

Treatment diet type (carbohydrate-fat-protein): Very low-high-high

Exercise component? No

Recipients: Abdominally obese participants, 68.9% female, aged 50.3 (8.4) with BMI 33.9 (4.3) and weight 94.4 (15.5)

Tay 2008 (Continued)

Why? VLCHF diet produces greater reductions in triacylglycerols (TAG) and increases in high-density lipoprotein cholesterol (HDL-C) and at least comparable changes in blood pressure and insulin resistance, without detrimental effects on low-density lipoprotein cholesterol (LDL-C) for periods up to 1 year.

What (materials)? Key foods for the macronutrient profile, comprising approximately 30% of energy, was provided for the first eight weeks. Thereafter \$40 food vouchers were given to participants for the next 16 weeks. Scales for weighing food were provided.

What (procedures)? Subjects were instructed to follow a very-low-carbohydrate diet and were given key foods for eight weeks and food vouchers for the following 16 weeks to assist with compliance. Semiquantitative food records were kept and food was weighed. A qualified dietitian provided individualised dietary advice, meal planning, and recipe information at each clinic visit. Three-day food records were kept every two weeks and dietary composition was determined. Dietary intake was assessed by food frequency questionnaire.

Who provided? Qualified dietitians provided individual consultations.

How and where? Face-to-face consultations with dietitians at a clinic and food records kept by participants at home

When and how much? During the course of the 24-week intervention subjects attended the clinic fortnightly for eight weeks and monthly thereafter. Key foods were provided on a fortnightly basis for eight weeks. Food vouchers were provided for the remaining 16 weeks on a monthly basis. Food records were completed daily and individual consultations with dietitians occurred during clinic visits. Three-day food records were done every two weeks and food frequency questionnaires were completed at baseline and 24 weeks.

Strategies to improve or maintain fidelity; tailoring and modification: Keeping of food records and analysis thereof for dietary composition, weighing of food, regular determination of body weight and plasma ketones as study outcome, regular meetings with dietitian, provision of key foods and food vouchers. Dietary advice was individualised. Subjects in the HCLF diet were asked to restrict saturated fat intake to < 10 g/day for the study duration.

Extent of intervention fidelity: High level of dietary compliance found according to dietary data and the level of plasma ketones

Concomitant interventions: In the total group, 17.0% were taking estrogen (12.5% HRT and 4.5% oral contraceptive), 30.7% were on antihypertensive medications, 20.5% were taking lipid-lowering medication and none were taking hypoglycemic medication; no significant differences between medication use in the two trial arms.

Control diet:

Name (as reported) and brief description: High-carbohydrate low-fat (HCLF) diet. 46% of total energy as carbohydrate, 24% as protein and 30% as total fat (< 8% saturated). Moderate energy restriction of 30% (prescription of 6000 kJ for women and 7000 kJ for men)

Control diet type (carbohydrate-fat-protein): Balanced-balanced-high

Exercise component? No

Recipients: Abdominally obese participants, 60.5% female, aged 51.0 (7.5) with BMI 33.5 (4.1) and weight 95.2 (12.6).

Why? Dietary recommendations for the management of weight and treatment of obesity are to follow a high-carbohydrate, low-fat, energy-restricted diet.

What (materials)? Key foods for the macronutrient profile, comprising approximately 30% of energy, were provided for the first eight weeks. Thereafter \$40 food vouchers were given to participants for the next 16 weeks. Scales for weighing food were provided.

What (procedures)? Subjects were instructed to follow a high-carbohydrate low-fat diet and were given key foods for eight weeks and food vouchers for the following 16 weeks to assist with compliance.

Tay 2008 (Continued)

Semiquantitative food records were kept and food was weighed. Individual consultations with a dietitian comprised dietary advice and meal planning. Three-day food records were kept every two weeks and dietary composition was determined. Dietary intake was assessed by food frequency questionnaire.

Who provided? Qualified dietitians provided individual consultations.

How and where? Face-to-face consultations with dietitians at a clinic and food records kept by participants at home

When and how much? During the course of the 24-week intervention subjects attended the clinic fortnightly for eight weeks and monthly thereafter. Key foods were provided on a fortnightly basis for eight weeks. Food vouchers were provided for the remaining 16 weeks on a monthly basis. Food records were completed daily and individual consultations with dietitians occurred during clinic visits. Three-day food records were done every two weeks and food frequency questionnaires were completed at baseline and 24 weeks.

Strategies to improve or maintain fidelity; tailoring and modification: Keeping of food records and analysis thereof for dietary composition, weighing of food, regular determination of body weight and plasma ketones as study outcome, regular meetings with dietitian, provision of key foods and food vouchers. Dietary advice was individualised. Subjects in the HCLF diet were asked to restrict saturated fat intake to < 10 g/day for the study duration.

Extent of intervention fidelity: High level of dietary compliance found according to dietary data

Concomitant interventions: In the total group, 17.0% were taking estrogen (12.5% HRT and 4.5% oral contraceptive), 30.7% were on antihypertensive medications, 20.5% were taking lipid-lowering medication and none were taking hypoglycemic medication; no significant differences between medication use in the two trial arms

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: Yes

Number of participants with 5% weight loss from baseline at ≥ 12 months: Yes

Change in BMI (kg/m²) at 3 to 12 months: Yes

Change in BMI (kg/m²) at ≥ 12 months: Yes

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: Yes

Change in SBP (mmHg) at ≥ 12 months: Yes

All-cause mortality at ≥ 12 months: No

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥ 12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: No

Change in LDL (mmol/L) at ≥ 12 months: Yes

Change in HDL (mmol/L) at ≥ 12 months: Yes

Tay 2008 (Continued)

Change in non-HDL (mmol/L) at \geq 12 months: Yes

Change in total cholesterol (TC) (mmol/L) at \geq 12 months: Yes

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at \geq 12 months: Yes

Participant-reported adverse effects: Yes

Participants

Country and setting: Australia, outpatient research organisation in Adelaide. Key food representative of the macronutrient composition, and totalling 30% of energy, were provided to participants for the first twelve weeks; and key foods or a 50 AUD voucher on alternate months following the 12 weeks.

Eligibility criteria: Participants were aged 35 to 68 years and were overweight or obese (defined as BMI of 26 to 45 kg/m²) with type 2 diabetes, defined as HbA1c \geq 7.0% or treated with diabetes medication. Participants were excluded if they had type 1 diabetes, impaired renal function or proteinuria; had abnormal liver function test or any overt endocrine problems (except treated and stable thyroid disease); history of malignancy; respiratory, gastrointestinal or cardiovascular disease; were pregnant or lactating; had clinical depression; had a history of or current eating disorder, or were an ex or current smoker.

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:
Name (as reported) and brief description: Low-carbohydrate (LC) diet. Planned macronutrient profiles of 14% carbohydrate (with the objective of restricting to < 50 g/d), 28% protein and 58% total fat (35% MUFA, 13% PUFA and < 10% saturated) plus structured exercise 60 min on three nonconsecutive days. Individualised energy prescription with moderate restriction (500–1000 kcal/day)

Treatment diet type (carbohydrate-fat-protein): Very low-high-high

Exercise component? Yes

Recipients: Subjects were 51% female, aged mean (SD) 58 (7) years, with BMI mean (SD) 35.1 (4.1), and weight 101.6 (15.8)kgs

Why? LC diet with high-unsaturated and low-saturated fat content may promote greater improvements in glycaemic control in T2DM without detrimental effects on LDL-C.

What (materials)? Participants were supplied key foods or AU\$50 food vouchers on alternate months.

What (procedures)? LC diet, 14% of total energy as carbohydrate (objective to restrict intake to 50 g/day), 28% protein, and 58% total fat. Under supervision of exercise professionals, participants undertook, free of charge, 60-min structured exercise classes on 3 nonconsecutive days per week, incorporating moderate exercise. Dietitians provided dietary advice and instruction on the eating plan and reporting requirements.

Who provided? Dietitian

How and where? Face-to-face individual sessions, location NR

When and how much? Biweekly sessions for 12 weeks then monthly sessions

Strategies to improve or maintain fidelity; tailoring and modification: Attendance records were kept and participants were encouraged to make up any missed sessions. Dietary intake and adherence were assessed from 7 consecutive days (including 2 weekend days) of daily weighed food records for every 14-day period. To facilitate compliance, participants met individually with a dietitian biweekly for 12 weeks and monthly thereafter. Participants undertook, free of charge, 60-min structured exercise classes.

Extent of intervention fidelity: Energy intake did not differ between groups (HC 1587 +/- 171 kcal; P = 0.56). Relative to the HC diet group, the LC diet group consumed less carbohydrate (LC 56.7 +/- 8.0 vs. HC 204.9 +/- 22.8 g; 14 +/- 2 vs. 50 +/- 2% total energy) and dietary fibre (24.7 +/- 3.5 vs. 31.1 +/- 3.2 g), more protein (102.8 +/- 14.7 vs. 73.6 +/- 8.3 g; 27 +/- 1 vs. 19 +/- 1% total energy), total fat (96.5 +/- 16.5 vs. 44.3 +/- 7.4 g; 54 +/- 3 vs. 25 +/- 3% total energy), saturated fat (10.0 +/- 0.9 vs. 7.5 +/- 1.1% total ener-

Tay 2014 (Continued)

gy), monounsaturated fat (30.4 +/- 1.8 vs. 11.5 +/- 1.3% total energy), polyunsaturated fat (12.2 +/- 1.1 vs. 4.1 +/- 0.6% total energy), and cholesterol (243 +/- 42 vs. 138 +/- 25 mg); P < 0.001 for all.

Concomitant interventions: After 24 weeks, the LC diet group experienced twofold greater reductions in the antiglycaemic MES, with more participants experiencing a reduction of 20% compared with HC diet group (P < 0.005). Six participants reduced (LC 4 and HC 2) and five increased (LC 3 and HC 2) lipid-lowering medication. Eleven participants reduced (LC 10 and HC 1) and six increased (LC 3 and HC 3) antihypertensive medication.

Control diet:

Name (as reported) and brief description: High-carbohydrate (HC) diet. Planned macronutrient profiles of 53% carbohydrate with emphasis on low GI foods, 17% protein and < 30% total fat (15% MUFA, 9% PUFA and < 10% saturated) plus structured exercise 60 min on three nonconsecutive days. Individualised energy prescription with moderate restriction (500–1000 kcal/day)

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? Yes

Recipients: Subjects were 36% female, aged mean (SD) 58 (7) years, with BMI mean (SD) 34.2 (4.5), and weight 101.7 (14.4)kgs.

Why? NR

What (materials)? Participants were supplied key foods or AU\$50 food vouchers on alternate months.

What (procedures)? HC diet, 53% carbohydrate with emphasis on low-glycaemic index foods, 17% protein, and 30% total fat. Under supervision of exercise professionals, participants undertook, free of charge, 60-min structured exercise classes on 3 nonconsecutive days per week, incorporating moderate exercise. Dietitians provided dietary advice and instruction on the eating plan and reporting requirements.

Who provided? Dietitian

How and where? Face-to-face individual sessions, location NR

When and how much? Biweekly sessions for 12 weeks then monthly sessions

Strategies to improve or maintain fidelity; tailoring and modification: Attendance records were kept and participants were encouraged to make up any missed sessions. Declaration of interest: "No potential conflicts of interest relevant to this article were reported."

Veum 2017
Study characteristics

Methods

Review comparison(s) addressed by this study: 1
Study design: RCT, parallel, single-centre (1)
Trial registry number: NCT01750021
Total number of trial arms: 2
Year trial started: 2012
Sample size calculation: No

Veum 2017 (Continued)

Outcome(s) used for sample size calculation: NA

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 12 weeks

What was the duration of the weight maintenance phase: NA

Other notes about methods: Post hoc power analysis indicated ~40% power for per protocol analysis and type II errors could not be ruled out.

Participants

Country and setting: Norway, outpatient university hospital in Bergen

Eligibility criteria: Male subjects with abdominal obesity, normal fasting blood glucose < 7 mmol/L, waist circumference > 98 cm, and BMI > 29 kg/m² or percentage body fat ≥ 25. Subjects were excluded if they had severe diseases, including inflammatory bowel diseases, known food allergies, were on regular medication (except for alkalinising gastric buffers), made attempts at systematic weight reduction over the previous six months, and/or regularly consumed > 2 units of alcohol per week.

Type 2 diabetes at baseline: No

Impaired glucose tolerance at baseline: Unclear

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Male

Total number randomised: 46

Total attrition in trial: 8

Treatment diet

Participants randomised: 24

Participants withdrawn (voluntary): 2

Total attrition: 4

Control diet:

Participants randomised: 22

Participants withdrawn (voluntary): 4

Total attrition: 4

Baseline data treatment diet:

Randomised participants not included: None

Age (years): mean (SD) 40.3 (5.53)

Gender distribution (as reported): female 0%, male 100%

Weight (kg): mean (SD) 112 (10.1)

BMI (kg/m²): mean (SD) 33.8 (2.5)

DBP (mmHg): mean (SD) 84.0 (9.1)

SBP (mmHg): mean (SD) 131 (14.2)

HbA1c (%): mean (SD) 5.58 (0.5)

LDL (mmol/L): mean (SD) 3.65 (1.14)

Veum 2017 (Continued)

HDL (mmol/L): mean (SD) 1.05 (0.30)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.35 (1.17)

TG (mmol/L): mean (SD) 1.52 (0.60)

Baseline data control diet:

Randomised participants not included: None

Age (years): mean (SD) 40.2 (4.50)

Gender distribution (as reported): female 0%, male 100%

Weight (kg): mean (SD) 111 (12.9)

BMI (kg/m²): mean (SD) 33.6 (3.4)

DBP (mmHg): mean (SD) 84.2 (7.9)

SBP (mmHg): mean (SD) 131 (16.2)

HbA1c (%): mean (SD) 5.62 (0.7)

LDL (mmol/L): mean (SD) 3.68 (1.07)

HDL (mmol/L): mean (SD) 1.23 (0.24)

Non-HDL (mmol/L): NR

TC (mmol/L): mean (SD) 5.42 (1.14)

TG (mmol/L): mean (SD) 1.45 (0.53)

Group differences at baseline: NR

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Age, HbA1c, LDL, HDL, total cholesterol and triglycerides baseline values were per protocol (missing 4/24 intervention and 4/22 control participants).

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Very high-fat low-carbohydrate (VHFLC) diet, with macronutrient profile of 10% (50 g) energy from carbohydrates, 17% (90g) from protein and 73% (170 g) from fat. All participants were asked to consume a total of 8750 kJ/d.

Treatment diet type (carbohydrate-fat-protein): Very low-high-balanced

Exercise component? No

Recipients: Abdominally obese men with normal fasting glucose aged 40.3 (5.53) years, with BMI 33.8 (2.5) kg/m² and weight 112 (10.1) kg.

Why? Low-carbohydrate has gained popularity, in part due to the temporary and long-term weight loss as well as improved insulin sensitivity. The health concerns surrounding this diet is possibly due to studies normally including energy-dense diets with considerable amounts of processed carbohydrates.

What (materials)? Food products donated by suppliers, i.e. butter, coconut fat, erythritol, stevia and mixes of almond flour and plant fibres. A comprehensive recipe booklet with > 225 recipes, with pre-

Veum 2017 (Continued)

calculated nutrient content and clear instructions for meal and snack preparation, participants could choose from.

What (procedures)? Before baseline assessments, the participants completed a half-day course at which they received detailed instructions on how to implement the recipe booklet system. Study visits at four, eight and 12 weeks with nutritionist and physician. Diet recording over five successive days each month for three months

Who provided? Nutritionists and physicians

How and where? Face-to-face meetings with nutritionist and physician at study visits. Diet recording online

When and how much? Intervention duration was three months. Meetings with nutritionist and physician for 15 minutes at each study visit (four, eight and 12 weeks); dietary recording over five successive days each month for three months

Strategies to improve or maintain fidelity; tailoring and modification: Participants were monitored closely and contacted regularly between study visits. They were also offered individual counselling if needed and completed diet recording each month. Recipe booklets were provided.

Extent of intervention fidelity: Actual macronutrient intakes at the end of the intervention were 56.1 (5.1) g carbohydrates (from per protocol analysis).

Concomitant interventions: NR

Control diet:

Name (as reported) and brief description: Low-fat high-carbohydrate (LFHC) diet, with macronutrient profile 53% (275 g) energy from carbohydrates, 17% (90 g) from protein and 30% (70 g) from fat. All participants were asked to consume a total of 8750 kJ/d.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Abdominally obese men with normal fasting glucose aged 40.2 (4.50) years, with BMI 33.6 (3.4) kg/m² and weight 111 (12.9) kg

Why? There is concern that low-carbohydrate diets increase the intake of total and saturated fat, leading to potential increases in visceral fat and promotion of NAFLD. Saturated fat is also linked to stimulation of increased circulating cholesterol levels, in particular LDL and non-HDL, as well as increased inflammation and interference with insulin signaling.

What (materials)? Food products donated by suppliers, i.e. butter, coconut fat, erythritol, stevia and mixes of almond flour and plant fibres. A comprehensive recipe booklet with > 225 recipes, with pre-calculated nutrient content and clear instructions for meal and snack preparation, participants could choose from.

What (procedures)? Study visits at four, eight and 12 weeks with nutritionist and physician. Diet recording over five successive days each month for three months

Who provided? Nutritionists and physicians

How and where? Face-to-face meetings with nutritionist and physician at study visits. Diet recording online

When and how much? Intervention duration was three months. Meetings with nutritionist and physician for 15 minutes at each study visit (four, eight and 12 weeks); dietary recording over five successive days each months for three months

Strategies to improve or maintain fidelity; tailoring and modification: Participants were monitored closely and contacted regularly between study visits. They were also offered individual counselling if needed and completed diet recording each month. Recipe booklets were provided.

Veum 2017 (Continued)

Extent of intervention fidelity: Actual macronutrient intakes at the end of the intervention were 281 (23.5) g carbohydrates (from per protocol analysis).

Concomitant interventions: NR

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: Yes

Change in BMI (kg/m²) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: No

Change in SBP (mmHg) at ≥ 12 months: No

All-cause mortality at ≥ 12 months: No

Cardiovascular mortality at ≥ 12 months: No

Non-fatal myocardial infarction at ≥ 12 months: No

Non-fatal stroke at ≥ 12 months: No

Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No

Change in HbA1c (%) at ≥ 12 months: No

Change in LDL (mmol/L) at ≥ 12 months: No

TG (mmol/L): mean (SD) 2.11 (0.66)

Group differences at baseline: NR

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Unrestricted/ad libitum prescription in both diets

Treatment diet:
Name (as reported) and brief description: Carbohydrate-restricted diet (CRD) consumed ad libitum, with the main goal to restrict carbohydrates to a level that induced ketosis

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? No

Recipients: Men and women with atherogenic dyslipidemia aged 32.6 (11.3) years, with BMI 33.5 (5.2) and weight 96.5 (13.7) kg

Why? It is hypothesised that carbohydrate restriction improves markers which define the metabolic syndrome through insulin regulation.

Volek 2009 (Continued)

What (materials)? Detailed booklets outlining dietary goals, listing appropriate food for the diet, recipes, meal plans and food record log sheets. A multivitamin and -mineral complex was provided. Urine reagent strips for testing ketosis

What (procedures)? Subjects were instructed to follow a carbohydrate-restricted diet by a registered dietitian. Two baseline visits were conducted prior to commencing intervention where participants' blood samples and assessments were taken following a 12-h overnight fast and 24-h abstinence from alcohol and strenuous exercise. These tests were repeated after 12 weeks of intervention. Dietary intake was assessed with detailed and weighed seven-day food records collected at baseline to assess habitual intake. Weekly follow-up counselling during in which body mass was measured, compliance was assessed, and further dietetic education was provided. Oral fat tolerance test and other blood analyses were also done. Seven-day weighed food records were kept during weeks 1, 6, and 12 of the intervention and were analysed for energy and macro/micronutrient content.

Who provided? Registered dietitians

How and where? Face-to-face

When and how much? Follow-up counselling was done weekly and monitoring of ketosis occurred daily for the duration of the 12-week intervention. In week one, six and 12 of the intervention seven-day weighed food records were kept.

Strategies to improve or maintain fidelity; tailoring and modification: Weighing before and after intervention, dietary intake assessed by detailed seven-day weighed food records, compliance was assessed during weekly counselling, ketosis was monitored. Subjects received individualised and personalised counselling.

Extent of intervention fidelity: High degree of compliance reported with urinary ketone levels above trace on 85% of days

Concomitant interventions: Multivitamins at levels < 100% of the RDA (one pill every other day)

Control diet:

Name (as reported) and brief description: Low-fat diet (LFD) consumed ad libitum, participants were instructed to consume < 10% of total calories from saturated fat and < 300 mg cholesterol daily. Macronutrient balanced of ~55% energy from carbohydrates, ~25% from fat and ~20% from protein

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Men and women with atherogenic dyslipidemia aged 36.9 (12.5) years, with BMI 32.1 (4.1) and weight 94.4 (15.2) kg

Why? "Low fat diets may be effective for weight loss..."

What (materials)? Detailed booklets outlining dietary goals, listing appropriate food for the diet, recipes, meal plans and food record log sheets. A multivitamin and -mineral complex was provided.

What (procedures)? Subjects were instructed to follow a low-fat diet by a registered dietitian. Two baseline visits were conducted prior to commencing the intervention where participants' assessments and blood samples were taken following a 12-h overnight fast and 24-h abstinence from alcohol and strenuous exercise. These tests were repeated after 12 weeks of intervention. weekly follow-up counselling during which body mass was measured, compliance was assessed, and further dietetic education was provided.  Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Higher-protein diet. Planned macronutrient distribution of 32% protein, 33% carbohydrate and 30% fat with < 10% saturated. Physical activity 150 min/week. Moderate energy restriction of ~30% of the individual estimated energy requirement

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Watson 2016 (Continued)

Exercise component? Yes

Recipients: Subjects were 47% female, aged mean (SD) 54 (8), BMI mean (SD) 34.3 (5.4) and weight 97.3 (17.1) kgs

Why? The aim of this study was therefore to compare the effects of isocaloric HP and HC diets, combined with regular moderate intensity exercise, on glycaemic control and cardiometabolic risk factors in overweight and obese adults with T2DM initially following 12 weeks of active weight loss, and then to re-evaluate the outcomes following 12 weeks of energy balance without the influence of weight change. By including an exercise component, we are able to determine the effects of the dietary patterns when administered as part of a holistic lifestyle intervention as recommended in the management of T2DM.

What (materials)? Core study foods corresponding to their assigned dietary pattern

What (procedures)? HP diet being 32% of total energy as protein, 33% carbohydrate, and 30% total fat (< 10% as saturated fat). Participants received comprehensive dietary advice every 2 weeks. 30 mins of moderate intensity aerobic exercise, 5 times a week.

Who provided? Dietitian

How and where? Face-to-face session, location NR

When and how much? Dietary intervention for 24 weeks; 12 weeks for weight loss and 12 weeks for maintenance. Participants attended clinic appointments at baseline and the end of each study phase (weeks 0, 12, and 24) for outcome assessments. Participants received comprehensive dietary advice from a qualified dietitian at baseline and every two weeks during the study. Daily semi-quantitative food records were completed to guide dietary intake and to permit subsequent dietary analysis. Throughout the study, participants were asked to undertake a minimum of 30 min of moderate intensity aerobic exercise, five times per week.

Strategies to improve or maintain fidelity; tailoring and modification: Daily semi-quantitative food records were completed to guide dietary intake and to permit subsequent dietary analysis. Participants completed physical activity logs to monitor compliance.

Extent of intervention fidelity: Total energy intake was similar between the groups for both intervention phases. Compared to the HC group, the HP group consumed significantly more protein and less carbohydrate and fibre ($P < 0.05$ for each nutrient) for each phase. As expected, the total fat intake in the HP diet was higher than the HC diet as a result of larger meat portions and the inclusion of reduced-fat cheese and almonds, however both groups met the dietary recommendations for saturated fat intake (< 10% of energy intake).

Concomitant interventions: 58% metformin; 19% insulin; 52% lipid-lowering medication; 61% antihypertensive medication

Control diet:

Name (as reported) and brief description: Higher-carbohydrate diet. Planned macronutrient distribution of 22% protein, 51% carbohydrate and 22% fat with < 10% saturated. Physical activity 150 min/week. Moderate energy restriction of ~30% of the individual estimated energy requirement

Control diet type (carbohydrate-fat-protein): Balanced-balanced-high

Exercise component? Yes

Recipients: Subjects were 45% female, aged mean (SD) 55 (8), BMI mean (SD) 34.4 (4.7) and weight 101.5 (16.6) kgs.

Why? NR

What (materials)? Core study foods corresponding to their assigned dietary pattern

Trial registry number: NR

Total number of trial arms: 2

Year trial started: 2004

Sample size calculation: Yes

Outcome(s) used for sample size calculation: Change in HbA1c

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 24 weeks

What was the duration of the weight maintenance phase: NA

Other notes about methods: NA

Participants

Country and setting: NR; likely USA based on authors and funders

Eligibility criteria: Participants were aged 18 to 65 years with BMI 27 to 50 kg/m² and type 2 diabetes for at least one year (defined as HbA1c > 6.0%) with onset after 15 years and no history of diabetic ketoacidosis; and with a desire to lose weight. Participants were excluded if they had an unstable or serious medical condition; significant comorbidities such as liver or kidney disease (defined as AST or ALT above 100 IU/L, or serum creatinine above 1.5 mg/dL); have cancer; were pregnant or nursing.

Type 2 diabetes at baseline: Yes

Impaired glucose tolerance at baseline: No

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Mixed

Total number randomised: 97

Total attrition in trial: 47

Treatment diet

Westman 2008 (Continued)

TC (mmol/L): mean (SD) 4.94 (1.13)

TG (mmol/L): mean (SD) 1.89 (1.42)

Group differences at baseline: "Another possible limitation is the baseline imbalance in the primary outcome, HbA1c, which occurred despite random allocation."

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate, ketogenic diet group intervention (LCKD), participants instructed to restrict intake of dietary carbohydrates to fewer than 20 g per day without explicit caloric restriction. Exercise recommended for 30 min three times a week

Treatment diet type (carbohydrate-fat-protein): Very low-unclear-unclear

Exercise component? Yes

Recipients: Subjects were 76.3% female, aged mean (SD) 51.8 (7.3), with BMI mean (SD) 37.7 (5.0), and weight 105.5 (19.5) kgs

Why? Dietary carbohydrate is the major determinant of postprandial glucose levels, and several clinical studies have shown that low-carbohydrate diets improve glycaemic control. In this study, we tested the hypothesis that a diet lower in carbohydrate would lead to greater improvement in glycaemic control over a 24-week period in patients with obesity and type 2 diabetes mellitus.

What (materials)? Lay-press diet book and additional handouts

What (procedures)? A registered dietitian instructed participants to restrict intake of dietary carbohydrate to fewer than 20 grams per day, without explicitly restricting caloric intake. The intervention for both groups included group sessions, diet instruction, nutritional supplements, and an exercise recommendation. Group meetings took place at an outpatient research clinic every week for 3 months, then every other week for 3 months. Participants were encouraged to exercise for 30 minutes at least 3 times per week, but no formal exercise programme was provided.

Who provided? Dietitian

How and where? Face-to-face, individual and group; research clinic

When and how much? Diet intervention for 6 months, Group meetings took place every week for 3 months, then every other week for 3 months.

Strategies to improve or maintain fidelity; tailoring and modification: Adherence with the diet and exercise recommendations was measured by self-report, food records, and urinary ketones.

Extent of intervention fidelity: Prior to the study intervention, the mean \pm SD dietary intake for both groups was 2128 \pm 993 kcal, 245 \pm 136 g of carbohydrate (46% of daily energy intake), 86 \pm 33 g of protein (18% of daily energy intake), 88 \pm 57 g of fat (36% of daily energy intake). Over the 24-week duration of the intervention, the LCKD group consumed 1550 \pm 440 kcal per day, 49 \pm 33 g of carbohydrate (13% of daily energy intake), 108 \pm 33 g of protein (28% of daily energy intake), 101 \pm 35 g of fat (59% of daily energy intake). There was no difference in self-reported exercise between the groups: the mean number of exercise sessions per week increased from 2.0 \pm 2.0 to 3.0 \pm 2.0 for the LCKD group.

Concomitant interventions: At baseline, 20 (95.2%) of the LCKD group were taking hypoglycemic medications (insulin + oral agents n = 4, insulin only n = 4, oral agents only n = 12). Twenty of 21 (95.2%) LCKD group participants had an elimination or reduction in medication. 4 in the LCKD group, who were taking over 20 units of insulin at baseline were no longer taking insulin at the end of the study.

Control diet:

Westman 2008 (Continued)

Name (as reported) and brief description: Low-glycaemic index diet group intervention (LGID), participants instructed to follow a low-GI reduced calorie diet with approximately 55% of daily caloric intake from carbohydrate. Exercise recommended for 30 min three times a week. The energy prescription was individualised to be 2100 kJ less than the participant's calculated energy intake for weight maintenance.

Control diet type (carbohydrate-fat-protein): Balanced-unclear-unclear

Exercise component? Yes

Recipients: Subjects were 80.4% female, aged mean (SD) 51.8 (7.8), with BMI mean (SD) 38.5 (5.6), and weight 106.3 (20.1) kgs.

Why? NR

What (materials)? Lay-press diet book and additional handouts

What (procedures)? A registered dietitian instructed participants to follow a low-glycaemic index, reduced-calorie diet with approximately 55% of daily caloric intake from carbohydrate. The intervention for both groups included group sessions, diet instruction, nutritional supplements, and an exercise recommendation. Group meetings took place at an outpatient research clinic every week for 3 months, then every other week for 3 months. Participants were encouraged to exercise for 30 minutes at least 3 times per week, but no formal exercise programme was provided.

Who provided? Dietitian

How and where? Face-to-face, individual and group; research clinic

When and how much? Diet intervention for 6 months, group meetings took place every week for 3 months, then every other week for 3 months.

Strategies to improve or maintain fidelity; tailoring and modification: Adherence with the diet and exercise recommendations was measured by self-report, food records, and urinary ketones.

Extent of intervention fidelity: Prior to the study intervention, the mean \pm SD dietary intake for both groups was 2128 \pm 993 kcal, 245 \pm 136 g of carbohydrate (46% of daily energy intake), 86 \pm 33 g of protein (18% of daily energy intake), 88 \pm 57 g of fat (36% of daily energy intake). Over the 24-week duration of the intervention, the LGID group consumed 1335 \pm 372 kcal per day, 149 \pm 46 g of carbohydrate (44% of daily energy intake), 67 \pm 20 g of protein (20% of daily energy intake), 55 \pm 23 g of fat (36% of daily energy intake). There was no difference in self-reported exercise between the groups: the mean number of exercise sessions per week increased from 2.2 \pm 2.2 to 3.8 \pm 2.9 for the LGID group ($P = 0.39$ for comparison).

Concomitant interventions: At baseline, 22 (75.9%) of the LGID group were taking hypoglycemic medications (insulin only $n = 3$, oral agents only $n = 19$), LCKD group participants had an elimination or reduction in medication, compared with 18 of 29 (62.1%) LGID group participants ($P < 0.01$). 1 in the LGID group who were taking over 20 units of insulin at baseline was no longer taking insulin at the end of the study.

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: No

Change in BMI (kg/m²) at 3 to 12 months: Yes

Change in BMI (kg/m²) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Westman 2008 (Continued)

Change in DBP (mmHg) at ≥ 12 months: No
Change in SBP (mmHg) at ≥ 12 months: No
All-cause mortality at ≥ 12 months: No
Cardiovascular mortality at ≥ 12 months: No
Non-fatal myocardial infarction at ≥ 12 months: No
Non-fatal stroke at ≥ 12 months: No
Diagnosis of type 2 diabetes mellitus at ≥ 12 months: No
Change in HbA1c (%) at ≥ 12 months: No
Change in LDL (mmol/L) at ≥ 12 months: No
Change in HDL (mmol/L) at ≥ 12 months: No
Change in non-HDL (mmol/L) at ≥ 12 months: No
Change in total cholesterol (TC) (mmol/L) at ≥ 12 months: No
Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at ≥ 12 months: No
Participant-reported adverse effects: Yes

Year trial started: 2008
Sample size calculation: No
Outcome(s) used for sample size calculation: NA
Duration of run-in period (weeks): NA
What was the duration of the weight loss phase: 16 weeks
What was the duration of the weight maintenance phase: NA
Other notes about methods: Post hoc power analysis indicated that the study was not powered for weight loss.

Wycherley 2010 (Continued)

Participants

Country and setting: Australia, outpatient research clinic in Adelaide. Key foods representing the macronutrient composition of each diet were provided every two weeks.

Eligibility criteria: Participants who were overweight or obese, sedentary and had type 2 diabetes. Participants were excluded if they had proteinuria; malignancy; a history of liver, kidney, cardiovascular, respiratory or gastrointestinal disease; uncontrolled hypertension; musculoskeletal injury or joint/peripheral vascular disease impeding exercise; were pregnant or lactating, a smoker or using insulin; or participated in physical exercise in the six months prior to the study.

Type 2 diabetes at baseline: Yes

Impaired glucose tolerance at baseline: No

Cardiovascular conditions/risk factors/events at baseline: No

Gender: Mixed

Total number randomised: 83

Total attrition in trial: 24

Treatment diet

Participants randomised: 21

Participants withdrawn (voluntary): 6

Other notes about participants: NA

Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: Higher-protein moderate-carbohydrate diet (HP). Target profile of 43% carbohydrate, 33% protein and 22% fat. Moderate energy restriction of 6000 kJ/day for women and 7000 kJ/day for men

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Exercise component? No

Recipients: Participants were diagnosed with impaired fasting glucose or T2DM according to guidelines with mean age 56.5 years, mean BMI 33.2 kg/m² and weight 102.7 (15.4) kg.

Why? Substitution of carbohydrate with protein in a energy-restricted low-fat (< 30%) diet may improve body composition and cardiovascular disease (CVD) risk factors including insulin sensitivity, glycaemic control, and blood lipids in study populations, such as those with type 2 diabetes.

What (materials)? Key foods were supplied that were representative of each diet's macronutrient profile- providing approx 50% total energy. Each participant received a scale to weight food quantities.

What (procedures)? Participants were assigned to a high-protein diet and provided with detailed dietary advice, meal planning and recipe information. Key foods representative of the macronutrient composition were supplied and participants were asked to weigh their food in order to complete a daily semi-quantitative food record. Provision of dietary advice, meal planning and recipe information at every session. Diets structured to include specific quantities of key foods to ensure correct macronutrient and energy intake

Who provided? Qualified dietitians provided meal planning, recipe information and detailed dietary advice; and also assessed dietary composition from food records.

Wycherley 2010 (Continued)

How and where? Face-to-face meetings with dietitians, location NR. Measurements were taken at research clinic.

When and how much? The duration of the intervention was 16 weeks, with meetings with a qualified dietitian every two weeks, duration NR. Seven consecutive days of food records were analysed every two weeks. Key foods representative of the macronutrient composition were provided every two weeks.

Strategies to improve or maintain fidelity; tailoring and modification: Weigh-in at 16 weeks, meetings every two weeks providing dietary advice, meal planning and recipe information to improve compliance, key foods were provided, food had to be weighed and food records kept, food records were analysed to assess compliance. A dietitian analysed dietary intake data from each participant, using data from 7 consecutive days from the semi-quantitative food record of each 2-week follow-up period.

Extent of intervention fidelity: Three of the 21 participants were excluded for non-compliance. The authors reported good compliance based on food records with significantly more protein and fewer carbohydrates consumed. A significant diet effect for urea-to-creatinine excretion ratio in urine was reported, with increase in high-protein group (31.1 (9.8) to 33.6 (11.2)).

Concomitant interventions: A total of 33.3% (n = 7) of participants were on hypoglycemic medication, 19.0% (n = 4) were on antihypertensive drugs and 23.8% (n = 5) were on lipid-lowering medication.

Control diet:

Name (as reported) and brief description: Standard carbohydrate, low-protein and low-fat diet (CON). Target profile of 53% carbohydrate, 19% protein and 26% fat. Moderate energy restriction of 6000 kJ/day for women and 7000 kJ/day for men

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Participants were diagnosed with impaired fasting glucose or T2DM according to guidelines with mean age 54.6 years, mean BMI 32.3 kg/m² and weight 97.0 (10.6) kg.

Why? Isocaloric energy-restricted low-fat diet to facilitate weight loss and improve cardiovascular disease (CVD) risk factors including insulin sensitivity, glycaemic control, and blood lipids in study population

What (materials)? Key foods were supplied that were representative of each diet's macronutrient profile- providing approx 50% total energy. Each participant received a scale to weigh food quantities.

What (procedures)? Participants were assigned to a standard carbohydrate, low-protein, low-fat diet and provided with detailed dietary advice, meal planning and recipe information. Key foods representative of the macronutrient composition were supplied and participants were asked to weigh their food and keep food records.

Who provided? Qualified dietitians provided meal planning, recipe information and detailed dietary advice; and also assessed dietary composition from food records.

How and where? Face-to-face meetings with dietitians, location NR. Measurements were taken at research clinic.

When and how much? The duration of the intervention was 16 weeks, with meetings with a qualified dietitian every two weeks, duration NR. Seven consecutive days of food records were analysed every two weeks. Key foods representative of the macronutrient composition were provided every two weeks.

Strategies to improve or maintain fidelity; tailoring and modification: Weigh-in at 16 weeks, meetings every two weeks providing dietary advice, meal planning and recipe information to improve compliance, key foods were provided, food had to be weighed and food records kept, food records were analysed to assess compliance. A dietitian analysed dietary intake data from each participant, using data from 7 consecutive days from the semi-quantitative food record of each 2-week follow-up period.

Wycherley 2010 (Continued)

Extent of intervention fidelity: One of the 19 participants were excluded for non-compliance. The authors reported good compliance based on food records. A significant diet effect for urea-to-creatinine excretion ratio in urine was reported, with decrease in control group (30.8 (8.6) to 26.7 (3.8)).

Concomitant interventions: A total of 57.9% (n = 11) of participants were on hypoglycemic medication, 47.4% (n = 9) were on antihypertensive drugs and 47.4% (n = 5) were on lipid-lowering medication.

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: NA

 Interventions

Energy (E) comparison of treatment vs control diets: Similar energy prescription/approach to restrict energy intake in both diets

Treatment diet:

Name (as reported) and brief description: High protein (HP) diet. Macronutrient profile of 35% protein, 40% carbohydrate and 25% fat (total 53 g, saturated 14 g). Energy prescription of 7000 kJ per day

Treatment diet type (carbohydrate-fat-protein): Low-balanced-high

Wycherley 2012 (Continued)

Exercise component? No

Recipients: Men only N = 57, mean (SE) age 50.1(1.2) years, mean (SE) weight 105.2 (1.9) kg, mean (SE) 33.8 (0.6) kg/m²

Why? Sex differences in protein kinetics have been previously documented; hence, whether comparable effects of HP diet previously observed in females are also experienced by males remains largely unknown. This requires urgent investigation as males have a higher proportion of visceral adipose tissue, and a greater risk of cardiometabolic diseases.

What (materials)? "Participants were supplied with a 2-week provision of diet-specific key foods, representing approximately 60% of the energy intake, to improve compliance and allow them to familiarize themselves with the food types and quantities utilized in the study. They were also supplied with digital weighing scales."

What (procedures)? Participants were prescribed a HP diet made up of protein 35% (142 g, roughly 1.30 g per kg per day), carbohydrate 40% (135 g), fat 25% (total 53 g, saturated 14 g). Within the HP diet the prescribed daily protein distribution was approximately 20% (13 g) during the morning, 30% (39 g) at lunch time and 60% (78 g) of protein during the afternoon/evening period. Guided by dietitians every two weeks then monthly. Participants received detailed dietary prescription, meal planning advice and recipe information. To further facilitate dietary compliance, the dietary patterns were structured into quantities of daily foods and presented as a food checklist.

Who provided? Dietitian

How and where? Face-to-face session at the research centre

When and how much? Dietary intervention for 52 weeks. At baseline, week 12 and at the end of the intervention (week 52), participants attended the clinic following an overnight fast for outcome assessment. Participants met individually with a qualified dietitian at baseline, and every 2 weeks during the first 12 weeks of the study and monthly thereafter.

Strategies to improve or maintain fidelity; tailoring and modification: Participants were required to keep daily semi-quantitative food records in which foods consumed with a variable weight were weighed using kitchen scales before recording and foods with a standard unit (i.e. slice of bread) were recorded without pre-weighing. Dietary intake was assessed using a computerised database (Foodworks Professional Edition, version 4, 1998; Xyris Software, Highgate Hill, Australia) based on the analysis of 3 nonconsecutive days (1 weekend day and 2 weeks days) of each 2-week period of diet-record data throughout the study. The composite value for dietary intake for weeks 0–12 and 12–52 (Table 2) was calculated as an average of the 2 week diet-record data blocks within each of the respective periods. To further facilitate dietary compliance, the dietary patterns were structured into quantities of daily foods and presented as a food checklist. Throughout weeks 0–12, participants were supplied with a 2-week provision of diet-specific key foods, representing approximately 60% of the energy intake, to improve compliance and allow them to familiarise themselves with the food types and quantities utilised in the study.

Extent of intervention fidelity: On the basis of food record data, participants in both groups showed good compliance to the prescribed diets. The diets were similar in total energy ($P > 0.05$) but participants in the HP diet group consumed less carbohydrate, and more protein and fat than those consuming the HC diet.

Concomitant interventions: Participants were excluded if they were taking hypoglycaemic medication or drugs which affect insulin sensitivity.

Control diet:

Name (as reported) and brief description: High-carbohydrate (HC) diet. Macronutrient profile of 17% protein, 58% carbohydrate and 25% fat (total 51 g, saturated 14 g). Energy prescription of 7000 kJ per day

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Wycherley 2012 (Continued)

Recipients: Men only N = 61, mean (SE) age 49.2 (1.2) years, mean (SE) weight 102.6 (1.8) kg, mean (SE) 32.7 (0.5) kg/m²

Why? NR

What (materials)? "Participants were supplied with a 2-week provision of diet-specific key foods, representing approximately 60% of the energy intake, to improve compliance and allow them to familiarize themselves with the food types and quantities utilized in the study. They were also supplied with digital weighing scales."

What (procedures)? Participants were prescribed a HC diet made up of protein 17% (88 g, roughly 0.85 g per kg per day), carbohydrate 58% (198 g), fat 25% (total 51 g, saturated 14 g) that was designed to reflect current conventional dietary recommendations. Guided by dietitians every two weeks then monthly

Who provided? Dietitian

How and where? Face-to-face session at the research centre

When and how much? Dietary intervention for 52 weeks. At baseline, week 12 and at the end of the intervention (week 52), participants attended the clinic following an overnight fast for outcome assessment. Participants met individually with a qualified dietitian at baseline, and every 2 weeks during the first 12 weeks of the study and monthly thereafter.

Strategies to improve or maintain fidelity; tailoring and modification: Participants were required to keep daily semi-quantitative food records in which foods consumed with a variable weight were weighed using kitchen scales before recording and foods with a standard unit (i.e. slice of bread) were recorded without pre-weighing. Dietary intake was assessed using a computerised database (Foodworks Professional Edition, version 4, 1998; Xyris Software, Highgate Hill, Australia) based on the analysis of 3 nonconsecutive days (1 weekend day and 2 weeks days) of each 2-week period of diet-record data throughout the study. The composite value for dietary intake for weeks 0–12 and 12–52 (Table 2) was calculated as an average of the 2-week diet-record data blocks within each of the respective periods. To further facilitate dietary compliance, the dietary patterns were structured into quantities of daily foods and presented as a food checklist. Throughout weeks 0–12, participants were supplied with a 2-week provision of diet-specific key foods, representing approximately 60% of the energy intake, to improve compliance and allow them to familiarise themselves with the food types and quantities utilised in the study.

Extent of intervention fidelity: On the basis of food record data, participants in both groups showed good compliance to the prescribed diets. The diets were similar in total energy ($P > 0.05$) but participants in the HP diet group consumed less carbohydrate, and more protein and fat than those consuming the HC diet.

Concomitant interventions: Participants were excluded if they were taking hypoglycaemic medication or drugs which affect insulin sensitivity.

 Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: Yes

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Number of participants with 5% weight loss from baseline at ≥ 12 months: Yes

Change in BMI (kg/m²) at 3 to 12 months: No

Change in BMI (kg/m²) at ≥ 12 months: No

Number of participants with 5% BMI reduction from baseline at 3 to 12 months: No

Number of participants with 5% BMI reduction from baseline at ≥ 12 months: No

Change in DBP (mmHg) at ≥ 12 months: Yes

Wycherley 2012 (Continued)

Change in SBP (mmHg) at \geq 12 months: Yes

All-cause mortality at \geq 12 months: No

Cardiovascular mortality at \geq 12 months: No

Non-fatal myocardial infarction at \geq 12 months: No

Non-fatal stroke at \geq 12 months: No

Diagnosis of type 2 diabetes mellitus at \geq 12 months: No

Change in HbA1c (%) at \geq 12 months: No

Change in LDL (mmol/L) at \geq 12 months: Yes

Change in HDL (mmol/L) at \geq 12 months: Yes

Change in non-HDL (mmol/L) at \geq 12 months: No

Change in total cholesterol (TC) (mmol/L) at \geq 12 months: Yes

Change in triglycerides (or triacylglycerides) (TG) (mmol/L) at \geq 12 months: Yes

Participant-reported adverse effects: Yes

Notes

Number and type of records(s): journal article

Trial acronym/name: None

Trial funded by: Meat and Livestock Australia through a project grant

Declaration of interest: "The authors declare no conflict of interest."

Yamada 2014
Study characteristics

Methods

Review comparison(s) addressed by this study: 3

Study design: RCT, parallel, single-centre (1)

Trial registry number: NR

Total number of trial arms: 2

Year trial started: 2011

Sample size calculation: Yes

Outcome(s) used for sample size calculation: Change in HbA1c

Duration of run-in period (weeks): NA

What was the duration of the weight loss phase: 6 months

What was the duration of the weight maintenance phase: NA

Other notes about methods: NA

Participants

Country and setting: Japan, outpatient clinic at hospital diabetes centre in Tokyo

Yamada 2014 (Continued)

Eligibility criteria: Participants with type 2 diabetes who had received guidance on caloric restriction at least once with an HbA1c level between 6.9 and 8.4%. Participants were excluded if they had specified ranges of proteinuria, serum creatinine, aspartate aminotransferase or alanine aminotransferase; had history of myocardial infarction or stroke in the past six months; experienced an absolute change in HbA1c of > 1.0% in the past six months or had ketosis (to avoid ketoacidosis as a complication).

Type 2 diabetes at baseline: Yes

Impaired glucose tolerance at baseline: No

Cardiovascular conditions/risk factors/events at baseline: Unclear

Gender: Mixed

Total number randomised: 24

Total attrition in trial: 0

Treatment diet

Participants randomised: 12

Participants withdrawn (voluntary): 0

Total attrition: 0

Control diet:

Participants randomised: 12

Participants withdrawn (voluntary): 0

Total attrition: 0

Baseline data treatment diet:

Randomised participants not included: None

Age (years): mean (SD) 63.3 (13.5)

Gender distribution (as reported): female 5/12, male 7/12

Weight (kg): mean (SD) 67.0 (15.9)

BMI (kg/m²): mean (SD) 24.5 (4.3)

DBP (mmHg): mean (SD) 72.6 (6.2)

SBP (mmHg): mean (SD) 124.4 (10.8)

HbA1c (%): mean (SD) 7.6 (0.4)

LDL (mmol/L): mean (SD) 2.58 (0.73)

HDL (mmol/L): mean (SD) 1.63 (0.44)

Non-HDL (mmol/L): NR

TC (mmol/L): NR

TG (mmol/L): mean (SD) 1.60 (0.86)

Baseline data control diet:

Randomised participants not included: None

Age (years): mean (SD) 63.2 (10.2)

Yamada 2014 (Continued)

Gender distribution (as reported): female 7/12, male 5/12

Weight (kg): mean (SD) 68.1 (7.7)

BMI (kg/m²): mean (SD) 27.0 (3.0)

DBP (mmHg): mean (SD) 74.8 (10.6)

SBP (mmHg): mean (SD) 124.9 (10.7)

HbA1c (%): mean (SD) 7.7 (0.6)

LDL (mmol/L): mean (SD) 2.91 (0.53)

HDL (mmol/L): mean (SD) 1.55 (0.49)

Non-HDL (mmol/L): NR

TC (mmol/L): NR

TG (mmol/L): mean (SD) 1.75 (0.98)

Group differences at baseline: No

Characteristic(s) with significant group difference and relevant statistic: NA

Other notes about participants: Patients are Japanese, BMI cutoff is different for overweight and obesity.

Interventions

Energy (E) comparison of treatment vs control diets: Different - ad libitum in treatment diet and restricted in control diet

Treatment diet:

Name (as reported) and brief description: Low-carbohydrate diet consumed ad libitum, total carbohydrate intake set at < 130 g/day but with a lower limit of 70 g/day to prevent ketosis. The intake was distributed across meals with 20 to 40 g/meal and 5 g of carbohydrates from sweets twice daily.

Treatment diet type (carbohydrate-fat-protein): Low-unclear-unclear

Exercise component? No

Recipients: Participants were type 2 diabetics, 41.7% female and aged 63.3 (13.5) years, with BMI 24.5 (4.3) and weight 67.0 (15.9) kg, mean HbA1c of 7.6%.

Why? The American Diabetes Association has recommended that controlling carbohydrate intake should form part of treating diabetes. The ADA has also recognised low-carbohydrate diets as an intervention which is effective for weight reduction. Dietary adherence to calorie-restricted diets may be difficult to sustain over the long term. Low carbohydrate diets may be used as a treatment option in diabetics as well as assist with weight loss, blood glucose and lipid management.

What (materials)? Recommendation as per Accurso et al (2008). Citation: Accurso A, Bernstein RK, Dahlgvist A, et al. Dietary carbohydrate restriction in type 2 diabetes mellitus and metabolic syndrome: time for a critical appraisal. *Nutr Metab (Lond)* 5: 9, 2008.

What (procedures)? Participants were assigned to the low-carbohydrate diet (> 70 g/day and < 130 g/day), with target carbohydrate contents per meal prescribed. Consultations with diet instructions and assessments every 2 months were conducted.

Who provided? Four registered dietitians instructed participants.

How and where? Face-to-face, location at outpatient clinics

When and how much? Intervention duration was six months with 2-monthly follow-up visits. Duration and frequency of instruction NR

Yamada 2014 (Continued)

Strategies to improve or maintain fidelity; tailoring and modification: NR

Extent of intervention fidelity: "The mean carbohydrate intake in the low carbohydrate group was < 130 g/day, suggesting that most patients were able to adhere to the meal instructions." Macronutrient intakes for carbohydrates, protein and fat were 29.8 (12.5)%, 25.3 (7.3)% and 45.4 (8.9)%.

Concomitant interventions: Participants were on insulin (25.0%), metformin (41.7%), sulfonylurea (41.7%), glinide (8.3%), thiazolidinedione (33.3%), alpha-glucosidase inhibitor (16.7%), DPP-4 inhibitor (16.7%). All participants were on some form of glucose-lowering drug; none were taking GLP-1.

Control diet:

Name (as reported) and brief description: Calorie-restricted diet as defined by the Japan Diabetes Society, with target macronutrient intakes of 50 to 60% carbohydrates, < 20% protein and < 25% fat. Target calorie intake was defined as total calorie intake (kcal) = ideal body weight × 25.

Control diet type (carbohydrate-fat-protein): Balanced-balanced-balanced

Exercise component? No

Recipients: Participants were type 2 diabetics, 58.3% female and aged 63.2 (10.2) years, with BMI 27.0 (3.0) and weight 68.1 (7.7) kg, mean HbA1c of 7.7%.

Why? The American Diabetes Association recognises caloric restriction as an effective strategy to reducing body weight. The Japan Diabetes Society also currently recommends caloric restriction for the management of blood glucose.

What (materials)? Recommendations of the Japan Diabetes Society. Citation: The Japan Diabetes Society. Diet therapy. In Practice Guideline for the Treatment for Diabetes in Japan; Nankodo: Tokyo, Japan, 2016; pp. 37–66. (In Japanese).

What (procedures)? Participants were assigned to caloric restriction and the calculation of calorie intake through the classification of macronutrients.

Who provided? Four registered dietitians instructed participants.

How and where? Face-to-face, location at outpatient clinics

When and how much? Intervention duration was six months with 2-monthly follow-up visits. Duration and frequency of instruction NR

Strategies to improve or maintain fidelity; tailoring and modification: NR

Extent of intervention fidelity: Macronutrient intakes for carbohydrates, protein and fat were 51.0 (4.6)%, 16.6 (2.8)% and 32.3 (5.2)%.

Concomitant interventions: Participants were on insulin (33.3%), metformin (8.3%), sulfonylurea (66.7%), thiazolidinedione (50.0%), DPP-4 inhibitor (25.0%). All participants were on some form of glucose-lowering drug; none were taking GLP-1, glinide or alpha-glucosidase inhibitor.

Outcomes

Change in body weight (kg) at 3 to < 12 months: Yes

Change in body weight (kg) at ≥ 12 months: No

Number of participants with 5% weight loss from baseline at 3 to < 12 months: No

Characteristics of studies awaiting classification *[ordered by study ID]*

[Aller 2019](#)

Methods	
Participants	Men and women aged 20 to 65 years, with BMI > 30
Interventions	High-protein and standard-protein hypocaloric diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

[Cui 2006](#)

Methods	
Participants	Obese subjects
Interventions	Low-carbohydrate and low-fat diets
Outcomes	Potential change in body weight
Notes	Placed under awaiting classification as no abstract or full text are available. Author correspondence yielded no response.

De Luis 2007

Methods	
Participants	Obese men and women
Interventions	Low-carbohydrate and low-fat diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2009a

Methods	
Participants	Men and women with BMI > 30
Interventions	High-fat/high-protein and low-fat diets
Outcomes	Short-term change in body weight, short-term change in BMI

Methods	
Participants	Obese men and women
Interventions	High-protein and standard-protein hypocaloric diets

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

330

De Luis 2016 *(Continued)*

Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2016a

Methods	
Participants	Men and women with BMI > 30
Interventions	High-protein and standard-protein hypocaloric diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2016b

Methods	
Participants	Obese subjects
Interventions	High-protein and standard-protein hypocaloric diets
Outcomes	Short-term change in body weight
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2017

Methods	
Participants	Men and women with BMI \geq 30
Interventions	Low-carbohydrate and low-fat diets
Outcomes	Short-term change in body weight, short-term change in BMI

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

-------	---

De Luis 2018

Methods	
Participants	Men and women aged 20 to 65 years, with BMI \geq 30
Interventions	Low-carbohydrate and low-fat diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2018a

Methods	
Participants	Men and women aged 20 to 65 years, with BMI of 30 to 45
Interventions	High-fat and low-fat diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2019

Methods	
Participants	Men and women aged 18 to 70 years, with BMI > 30
Interventions	High-protein and standard-protein severe hypocaloric diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

De Luis 2019 *(Continued)*

under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2019a

Methods	
Participants	Men and women aged 25 to 65, with BMI \geq 30
Interventions	High-fat and low-fat diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2020

Methods	
Participants	Adults aged 18 to 70 years, with BMI \geq 30
Interventions	High-protein and standard-protein severe hypocaloric diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

De Luis 2020a

Methods	
Participants	Men and women aged 20 to 60 years, with BMI \geq 30
Interventions	High-fat and low-fat diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

333

De Luis 2021

Methods	
Participants	Men and women aged between 25 and 65 years, with BMI ≥ 30 kg/m ²
Interventions	High-protein/low-carbohydrate and standard-protein severe hypocaloric diets
Outcomes	Short-term change in body weight, short-term change in BMI
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.

Evangelista 2009

Methods	
Participants	Men and women aged 59 (± 10) years, with heart failure and BMI > 27
Interventions	High-protein and standard-protein diets
Outcomes	Short-term change in body weight
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on the same participants from another reference by the same author; reference shares considerable similarity with other reference by the same author also placed under awaiting classification. Attempts to contact the author yielded no response. No protocol or prospective trial registry could be found.

Evangelista 2017

Methods	
Participants	Men and women aged 58.8 (± 9.7) years, with heart failure and mean BMI of 37 (± 6.2)
Interventions	High-protein and standard-protein diets
Outcomes	Short-term change in body weight
Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on the same participants from another reference by the same author; reference shares considerable similarity with other reference by the same author also placed under awaiting classification. Attempts to contact the author yielded no response. No protocol or prospective trial registry could be found.

Fernandez 2020

Methods	
Participants	Men and women with mean (SD) age 52.3 (13.1) years, with BMI > 30 kg/m ²
Interventions	Optimal-protein, carbohydrate-restricted and standard low-fat, low-calorie, guideline-based diets
Outcomes	Short-term change in body weight
Notes	Placed under awaiting classification as dietary composition could not be assessed from this conference abstract.

Fleming 2002

Methods	
Participants	Men and women
Interventions	High-fat and moderate-fat diets
Outcomes	Short-term change in body weight; long-term change in body weight; long-term changes in LDL, HDL and total cholesterol; long-term change in triglycerides
Notes	Placed under awaiting classification due to important inconsistencies in the reporting. Attempts to contact the author for clarity yielded no response. No protocol or prospective trial registry could be found.

Greene 2004

Methods	
Participants	Men and women
Interventions	Very low-carbohydrate and low-fat diets
Outcomes	Short-term change in body weight
Notes	Placed under awaiting assessment as the conference abstract was the only source of information, with data not in a usable format. Attempts to contact the author yielded no results, but a co-author indicated that the study was never published in full.

Izaola 2019

Methods	
Participants	Men and women aged 18 to 70 years, with BMI ≥ 30
Interventions	High-protein and standard-protein hypocaloric diets
Outcomes	Short-term change in body weight, short-term change in BMI

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

335

Izaola 2019 *(Continued)*

Notes	Placed under awaiting classification to avoid potential double-counting. We are uncertain if this is a distinct trial or reporting on a subsample of participants from other references by the same author; reference shares considerable similarity with other references by the same author also placed under awaiting classification. Author correspondence did not provide the required detail to preclude potential double-counting. No protocol or prospective trial registry could be found.
-------	---

Mukhtar 2009

Methods	
Participants	Subjects with metabolic syndrome
Interventions	Low-carbohydrate/high-protein and low-fat/high-carbohydrate diets
Outcomes	Potential short-term change in body weight; long-term change in body weight, triglycerides, HDL cholesterol and HbA1c
Notes	Placed under awaiting assessment as the conference abstract was the only source of information, with no usable data. Attempts to locate the first author yielded no results, contact with a co-author yielded no response.

Sun 2019

Methods	
Participants	Overweight adults
Interventions	Low-carbohydrate, calorie-restricted and 'normal' diets
Outcomes	Short-term change in body weight
Notes	Placed under awaiting assessment as the conference abstract was the only source of information, with no usable data. Attempts to locate the first author yielded no results.

BMI: body mass index

HbA1c: haemoglobin A1c/glycated haemoglobin

HDL: high-density lipoprotein(-cholesterol)

LDL: low-density lipoprotein(-cholesterol)

SD: standard deviation

Characteristics of ongoing studies *[ordered by study ID]*
NCT03832933

Study name	Comparing high- and normal-protein diets for the dietary remission of type 2 diabetes
Methods	Randomised trial (parallel assignment)
Participants	Males and females aged > 18 years, T2D diagnosis within previous 6 years (documented physician diagnosis, use of anti-diabetic medication, fasting glucose \geq 126 mg/dL, and/or HbA1c \geq 6.5%), BMI of > 27 kg/m ² , weight stable (+/- 3 kgs in the last 3 months), participants using GLP-1 agonists or SGLT-inhibitors must be on a stable (\geq 3 months) medication dosage and not be planning to change

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

336

NCT03832933 (Continued)

medication dosage, and willing and able to participate in a weekly group class for the first 16 weeks of the study, biweekly classes for the remainder of the study, and willing to participate in 4 study visits over the 52-week study period. Exclusion criteria: HbA1c concentrations of > 12%, pregnant or lactating within the past 6 months or trying to become pregnant, individual following a vegetarian/vegan only diet, food allergies (to red meats or other common protein sources), using exogenous insulin for T2D management, taking other medication that could cause weight loss or weight gain (such as steroids, tricyclic antidepressants, chemotherapy, antipsychotics, prescribed or OTC weight-loss agents). Oral contraceptives can be used as long as subject agrees to not change use of these during the study. Vitamins and minerals that do not have a weight effect are allowed as long as use is continued without change during the study. Current alcohol or drug abuse or dependence (subjects who have quit smoking in the last 6 months) will be excluded. Smokers whose smoking habits have been stable for the last 6 months and which remain stable during the study can be included, current eating disorder (anorexia or bulimia), any medical condition for which following a high-protein diet and/or 70 minutes of exercise daily would be inadvisable and untreated or unstable hypothyroidism. Thyroid medications must be stable for at least 3 months.

Interventions	Interventions - High-protein diet: 16-week weight-loss and 36-week weight-loss maintenance intervention. Approximate macronutrient distributions (carbohydrate:protein:fat) will be 32%:40%:28%. Control - Standard-protein diet: 16-week weight-loss and 36-week weight-loss maintenance intervention. Approximate macronutrient distribution (carbohydrate:protein:fat) will be 53%:21%:25%.
Outcomes	Primary outcomes: 1) change in body weight (baseline to 16 and 52 weeks) Secondary outcomes: 1) change in type 2 diabetes mellitus diagnosis (baseline to 52 weeks), 2) change in percentage body fat (baseline to 16 and 52 weeks), 3) change in percentage fat-free mass (baseline to 16 and 52 weeks)
Starting date	July 2019
Contact information	Drew Sayer, PhD, 205-354-8950, sayerd@uab.edu
Notes	Prospectively registered

NCT04014296

Study name	Weight loss in adults over 50 with obesity
Methods	Randomised trial (parallel assignment)
Participants	Females, ages > 50 years, post-menopausal with a BMI of 35 to 50 kg/m ² . Exclusion criteria included: untreated hyper or hypotension, cancer (except basal cell), gastrointestinal disorders affecting food intake, > 6 months of stable use of medications that affect metabolism, body weight, energy expenditure or appetite, current eating disorder (e.g. binge eating disorder, anorexia, or bulimia) and any medical condition for which following a HP diet, and/or 70 minutes of exercise daily would be inadvisable.
Interventions	Intervention - High-protein diet: 16-week weight loss programme with high-protein diet and supervised flexibility and balance training. Approximate macronutrient distributions (carbohydrate:protein:fat) will be 32%:40%:28%. Control - Resistance training: 16-week weight-loss programme with normal protein diet and supervised resistance training. Approximate macronutrient distributions (carbohydrate:protein:fat) will be 53%:20%:26%.
Outcomes	Primary outcomes: 1) change in fat mass (baseline to 8 and 16 weeks), 2) change in fat free mass (baseline to 8 and 16 weeks)

NCT04014296 (Continued)

Secondary outcomes: 1) change in glucose, 2) change in insulin, 3) change in lipids, 4) change in disposition index (oral glucose tolerance testing), 5) change in aerobic fitness, 6) change in physical activity, 7) change in muscle health and overall strength (all: baseline to 8, 16 and 52 weeks) 8) change in body composition (16 to 52 weeks)

Starting date	March 2020

Notes	Prospectively registered

NCT04023942

Study name	Personalised nutrition and e-health: lifestyle intervention study for weight loss maintenance (LION)
Methods	Randomised trial (parallel assignment)
Participants	Men and women aged 18 to 65 years with a BMI of 30-39.9 kg/m ² , owner of a smartphone, Caucasian with no severe diseases and with the ability to give written informed consent. Exclusion criteria include: diabetes mellitus, severe cardiovascular and/or respiratory disease, untreated high blood pressure, severe kidney disease, active cancer (or in remission), inflammatory bowel disease, severe chronic infections and/or inflammations, severe mental-health disorders, neurodegenerative disorders, endocrine diseases, lipoedema, pregnancy and lactation, vigorous weight fluctuations (> 5kgs) in the last 3 months, immobility, surgery in the last 3 months, participation in other intervention studies, carrier of pacemakers, blood donation or transfusions in the last 3 months
Interventions	Intervention - Low-carbohydrate (app-based group): Low-carbohydrate is defined as 30 per cent energy from carbohydrates and consists of 20 per cent energy from protein. The daily energy requirement is calculated for each participant individually, based on his/her resting metabolic rate and physical activity level. Daily energy intake should be 10% lower than the calculated daily energy requirement. Participants assigned to the app-based group works together with a personal coach via app, providing nutritional guidance and support during the 12-month weight-maintenance step. Low-carbohydrate (newsletter-based group): Low carbohydrate is defined as 30 per cent energy from carbohydrates and consists of 20 per cent energy from protein. The daily energy requirement is calculated for each participant individually, based on his/her resting metabolic rate and physical activity level. Daily energy intake should be 10% lower than the calculated daily energy requirement. The newsletter intervention group gets regularly digital newsletters, in the same frequency as 'contacts' take place in the app-based group.
Outcomes	Primary outcome: Weight maintenance 12 months after weight-loss intervention (15 months) Secondary outcomes: 1) weight change after eight weeks of formula diet (3 months), 2) change in glucose, 3) change in insulin, 4) change in lipids, 5) change in leptin (all at 0, 3, 6, 9, 12, 15 and 27 months), 6) change in resting metabolic rate, 7) change in magnetic resonance imaging (both at 0, 3, 15 and 27 months), 8) change in postprandial insulin, glucose and lipid responses (all at 0 months)
Starting date	17 July 2019

Notes	Retrospectively registered

NCT04136093

Study name	Diet for the maintenance of weight loss and metabolic health in obese postmenopausal women (WELCOME)
Methods	Randomised trial (parallel assignment)
Participants	Females aged 50-65 years who are all postmenopausal, with the absence of menses of over 12 months or serum follicle stimulating hormone > 30 IU/mL, with central obesity waist circumference (WC) > 80 cm, with low physical activity, who wished to lose weight and weight-loss maintenance, and have at least one other criterion of metabolic syndrome: increased systolic blood pressure \geq 130 mm Hg or high blood pressure diastolic \geq 85 mm Hg or ongoing treatment of previously diagnosed hypertension, increased serum triglyceride levels above > 150 mg/dL (1.7 mmol/L) or ongoing therapy hypertriglyceridemia, decreased HDL cholesterol < 50 mg/dL (1.3 mmol/L), and fasting blood glucose > 100 mg/dL (5.6 mmol/L) or ongoing treatment of previously diagnosed type 2 diabetes. Exclusion criteria: thyroid disease (hypothyroidism, hyperthyroidism, thyroiditis), hypercortisolism, Cushing's syndrome, kidney diseases, type 1 diabetes, asthma treated with oral and injectable steroids, cancers, mental disorders, New York Heart Association (NYHA) Class II heart failure, as well as any drug known to influence liver function, endocrine disorders, hormonal replacement therapy, significant weight change in the 6 months prior to the current study, impaired absorption of nutrients (celiac disease, inflammatory bowel disease), intolerance or food allergy to key components of the intervention diets, smoking and excessive alcohol consumption (consumption of more than 2 alcohol units per day - one alcohol unit equals one bottle of beer (340 g) or one glass of wine (140 g) or one glass of spirits (42.5 g of 40% spirit)
Interventions	Intervention - the MED diet: The MED diet will be composed of the basis food items traditional for the Mediterranean region i.e. olive oil, nuts, vegetables, fruits, and fish and this diet will be given an ad libitum approach. The MED diet will be giving a higher proportion of fat, at least 40% of the total energy, with 20% of the total energy from MUFAs, and less proportion of carbohydrates. To ensure the assumed supply of MUFAs and polyunsaturated fatty acids (PUFAs), the participants will be asked to consume a daily intake of 60 g (6 spoons) of extra virgin olive oil and 30 g (6 pieces) walnuts. Control - the DASH diet: The DASH diet will be giving a higher proportion of carbohydrates, at least 60% of total energy and less fat. The DASH diet will be composed of wholegrain cereal products, fruit, vegetables, low-fat dairy products, fish, seafood, poultry, beans, seeds and nuts and will be recommending eating of the traditional Polish food items, for example, oatmeal, rye bread, barley groats, apples, plums, etc. and reducing the supply of salt, sweets, sugars, fats especially saturated fats and red meat. In our study, the DASH diet will be given an ad libitum approach. The sufficient supply of carbohydrates and β glucans in the DASH diet will be ensured by daily consumption at least 50 g oatmeal and 50 g of barley groats.
Outcomes	<p>Primary outcomes: 1) change in body weight, 2) change in waist circumference, 3) change in fat mass (all at 8, 12, 16, 20, 24, 28, 32 and 52 weeks), 4) change in HDL cholesterol, 5) change in triglycerides, 6) change in glucose (all at 8, 32 and 52 weeks), 7) changes in systolic and diastolic blood pressure (both at 8, 12, 16, 20, 24, 28, 32 and 52 weeks)</p> <p>Secondary outcomes: 1) change in physical activity level, 2) change in eating behaviour (both at 8, 32 and 52 weeks), 3) change in adherence to prescribed diet, 4) change in dietary intake (both at 8, 12, 16, 20, 24, 28, 32 and 52 weeks)</p>
Starting date	February 2020

Notes	Prospectively registered

NCT04192357

Study name	A randomised controlled trial of a weight loss maintenance program for adults with obesity
Methods	Randomised trial (parallel assignment)
Participants	Men and premenopausal women (self-reported) aged 18 to 50 years with a BMI of > 30 kg/m ² and < 39.9kg/m ² , interested in being enrolled in a weight-loss programme and available to comply with study protocol and sign informed consent. Exclusion criteria included: pregnant, breastfeeding or planning to become pregnant within study period, menopausal women, subjects with chronic inflammatory bowel disease (clinical history of Crohn's disease, ulcerative colitis, irritable colon and diverticulitis), subjects with hormonal or thyroid pathology (hyper and hypothyroidism where TSH is not within normal range), subjects with renal impairment, subjects with chronic liver disease other than non-alcoholic hepatic steatosis, subjects with autoimmune diseases and/or chronic use of corticosteroids, use of weight-loss medications/other nutritional supplements, subjects with psychiatric illness, subjects sensitive to any component of supplements, subjects with surgery or hospitalisation in the last 30 days, subjects prescribed with more than 2 antidepressants or more than 2 drugs for hypercholesterolemia, subjects currently smoking, use of drugs with impact on lipid profile, previous attempt to lose weight in the last month and/or weight loss of more than 10 kg in the 3 months prior to the start of the study, and subjects with excessive alcohol consumption (self-reported: drinking more than 3 glasses of wine/day - or equivalent)
Interventions	Intervention - M3F program: the M3F programme is divided into three phases, with the first two being weight loss and the third phase being weight maintenance. Control - Low-carb diet: The low-carb diet programme is divided into two phases with the first being weight loss which follows a low-carb diet, and a second phase being weight maintenance.
Outcomes	Primary outcome: change in weight (at 72 weeks) Secondary outcomes: 1) change in total fat mass, 2) change in waist circumference, 3) change in body mass index, 4) change in systolic and diastolic blood pressure, 5) change in intestinal microbiota (bacterial DNA 16SRNA gene) (all at 72 weeks)
Starting date	February 2020

Notes	Prospectively registered

NCT04230928

Study name	Giving a low carbohydrate diet to overcome hypertension (GLOH)
Methods	Prospective randomised 2-group trial (parallel assignment)
Participants	Men and women aged > 18 years, willing to participate in a 10-month study, systolic blood pressure > 120 mm/Hg +/- diastolic blood pressure > 80 mm/Hg and African-American race. Exclusion criteria: diagnosed congestive heart failure, hypertension stage 4 or higher, received or needing more than 3 antihypertensive medications, pregnant or planning to become pregnant, receiving or needing a heart transplant, using injected long or short-acting insulin for diabetes treatment, not African-American race, unable to speak and read English with fluency
Interventions	Intervention - Very low-carbohydrate (VLC) diet: Individuals will receive a version of the Diabetes Prevention Program-Group Lifestyle Balance (DPP-GLB) programme in which 4 of the 12 modules will teach a very low-carbohydrate diet. All other components of the DPP-GLB will follow the standard programme. Control - Standard diet: Individuals will receive a version of the Diabetes Preven-

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

NCT04230928 (Continued)

tion Program-Group Lifestyle Balance (DPP-GLB) program in which 4 of the 12 modules will teach a standard very low-fat, calorie-restricted diet.

Outcomes	<p>Primary outcomes: 1) changes in systolic blood pressure, 2) dietary changes in carbohydrate intake (both at baseline, 12 weeks and 10 months)</p> <p>Secondary outcomes: 1) change in fasting blood glucose, 2) change in haemoglobin A1c, 3) change in cholesterol and lipoproteins, 4) change in percentage body weight, 5) change in body mass index, 6) dietary changes in fat and caloric intake, 7) change in diastolic blood pressure (all at baseline, 12 weeks and 10 months)</p>
Starting date	1 February 2020

NCT04382183

Study name	Impact of ketogenic diets in preventing relapse in obesity management (Ketomaintain)
Methods	Prospective randomised 2-group trial (parallel assignment)
Participants	<p>Healthy male and female volunteers aged 18 to 65 years, stable weight over the last three months (< 2 kg fluctuation), not currently dieting with the intention to lose weight, inactive lifestyle (< 150 min physical activity per week). Women should be taking oral contraceptives, with regular menstrual cycles, or be postmenopausal; as appetite and resting metabolic rate have been shown to be affected by the phase of menstrual cycle in normally ovulating women. Exclusion criteria: pregnancy, breastfeeding, drug or alcohol abuse within the last two years, clinically significant illness (including diabetes; gastrointestinal, kidney (GFR < 60 mL/min) or liver disease; osteoporosis (T-score < -2.5) or osteopenia (T-score < -1.5)), treatment with anti-osteoporotic drug, depression or other psychological disorders, eating disorders, milk intolerance, current medication known to affect appetite, metabolism or induce weight loss, planned surgery during the study period and participating in another research study</p>
Interventions	<p>Intervention - Ketogenic weight-loss maintenance group, following a ketogenic diet (50 g CHO/day) plant-based for 1 year. Control - Isocaloric balanced weight-loss maintenance group, following the standard Norwegian Health Directorate recommendations for 1 year</p>
Outcomes	<p>Primary outcome: body weight regain (at baseline, 5 weeks, 6 months and 1 year)</p> <p>Secondary outcomes: 1) fasting lipid profile, 2) bone mineral density (both at baseline, 6 months and 1 year)</p>
Starting date	3 August 2020

NCT04699448

Study name	Gene-diet interactions on body weight regulation and lifestyle parameters (iMPROVE)
Methods	Randomised trial (parallel assignment)
Participants	Men and women, aged 18 to 65 years, with a BMI of > 25 kg/m ² . Exclusion criteria included: pregnancy or lactation; the presence of comorbidities such as type 1 or 2 diabetes, cardiovascular disease, gastrointestinal disorders, mental illness or dietary disorders; taking dietary supplements aimed at body weight loss; or parallel participation in a different research study.
Interventions	Intervention - High-protein hypocaloric diet: 6-month diet designed for body weight loss. Approximate macronutrient distributions (carbohydrate: protein:fat) will be 30%:40%:30%. Control- High-carbohydrate hypocaloric diet: 6-month diet designed for body weight loss. Approximate macronutrient distributions (carbohydrate: protein:fat) will be 60%:18%:22%.
Outcomes	Primary outcomes: 1) change in body weight Secondary outcomes: 1) change in body fat percentage, 2) change in waist circumference, 3) change in visceral fat, 4) change in biochemical biomarkers related to metabolic syndrome and cardiovascular disease risk (i.e. total cholesterol, glucose, triglyceride and HDL levels), 5) change in sleep quality, 6) change in depression symptoms, 7) change in overall health status
Starting date	April 2020

Notes	Retrospectively registered

NCT04745572

Study name	Development of an adaptive treatment for weight loss in people with prediabetes
Methods	Randomised trial (sequential assignment)
Participants	Adults aged 18 to 75 years, with a BMI of ≥ 27 kg/m ² and at risk for developing type 2 diabetes mellitus (prediabetes). Exclusion criteria included: pregnancy, planned pregnancy or breastfeeding; or uncontrolled hypo- or hyperthyroidism.
Interventions	Intervention - Reduced-carbohydrate diet: response assessed at four weeks on a State of Slim (SOS) weight management programme combined with a reduced-carbohydrate (RC) diet; responders to continue and non-responders re-randomised to RC with time-restricted eating (TRE) or RC with structured exercise counselling sessions. Control - High-carbohydrate diet: response assessed at four weeks on a State of Slim (SOS) weight management programme combined with a high-carbohydrate (HC) diet; responders to continue and non-responders re-randomised to HC with time-restricted eating (TRE) or HC with structured exercise counselling sessions
Outcomes	Primary outcomes: 1) change in body weight, 2) change in glucose, 3) change in insulin, 4) change in lipids, 5) change in fat mass, 6) changes in QUICKI index (predictor of insulin resistance) Secondary outcomes: 1) change in overall strength, 2) change in aerobic fitness, 3) diet intake and physical activity monitoring
Starting date	May 2021

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

342

NCT04745572 (Continued)

Notes

Prospectively registered

BMI: body mass index
 CHO: carbohydrate
 DASH: Dietary Approaches to Stop Hypertension
 DNA: deoxyribonucleic acid
 DPP-GLB: Diabetes Prevention Program-Group Lifestyle Balance
 GFR: glomerular filtration rate
 GLOH: Giving a low carbohydrate diet to overcome hypertension (trial acronym)
 GLP-1: glucagon-like peptide-1
 HbA1c: haemoglobin A1c/glycated haemoglobin
 HC: high-carbohydrate
 HDL: high-density lipoprotein(-cholesterol)
 HP: high-protein
 LDL: low-density lipoprotein(-cholesterol)
 LION: Lifestyle intervention study for weight loss maintenance (trial acronym)
 MED: Mediterranean
 MUFA: monounsaturated fatty acid
 NYHA: New York Heart Association
 OTC: over-the-counter
 PUFA: polyunsaturated fatty acid
 RC: reduced-carbohydrate
 SD: standard deviation
 SGLT: sodium-glucose cotransporter
 SOS: State of Slim
 T2D: type 2 diabetes
 TRE: time-restricted eating
 TSH: thyroid stimulating hormone
 VLC: very low-carbohydrate
 WC: waist circumference
 WELCOME: Diet for the maintenance of weight loss and metabolic health in obese postmenopausal women (trial acronym)

RISK OF BIAS

Legend: Low risk of bias High risk of bias Some concerns

Risk of bias for analysis 1.1 Change in body weight (kg) at 3 to < 12 months

Study	Bias					Overall
	Randomisation process	Deviations from intended interventions	Missing outcome data	Measurement of the outcome	Selection of the reported results	
Aude 2004						
Bales 2017

Table 4. Trials without usable data for outcomes in Summary of findings tables in Comparisons 1 and 2

Outcomes included in Summary of Findings tables	Included studies that are believed to have measured the outcome, but did not report it in a usable format
Change in body weight (kg) at three to < 12 months	Foster 2003; Kitabchi 2013; Ruth 2013; Stentz 2016: reported as percentage change in weight, data not provided when authors contacted

Table 4. Trials without usable data for outcomes in Summary of findings tables in Comparisons 1 and 2 (Continued)

	<p>Mellberg 2014; Pittas 2005; Racette 1995; Samaha 2003: reported in a figure, data not provided when authors contacted</p> <p>Juanola-Falgarona 2014: BMI reported as per the published protocol; change in weight data not provided when authors contacted</p> <p>Ooi 2021: did not report data from baseline to the end of the weight-maintenance phase, only from the start to the end of the weight-maintenance phase of 8 weeks</p>
Change in body weight (kg) at ≥ 12 months	<p>Calleja-Fernández 2012: reported as percentage change in weight; data not provided when authors contacted</p> <p>Mellberg 2014: reported in a figure; data not provided when authors contacted</p>
Number of participants per group with weight loss of at least 5% at ≥ 12 months	Sacks 2009 : narrative range reported across all groups randomised and not per group; data not provided when authors contacted
Cardiovascular mortality at ≥ 12 months	None
Change in DBP (mmHg) at ≥ 12 months	None
Change in LDL cholesterol (mmol/L) at ≥ 12 months	Layman 2009 : unreadable values reported in a figure only; data not provided when authors contacted
Constipation at three to < 12 months	None

Table 5. Trials without usable data for outcomes in Summary of findings tables in Comparisons 3 and 4

Outcomes included in Summary of Findings tables	Included studies that are believed to have measured the outcome, but did not report it in a usable format
Change in body weight (kg) at three to < 12 months	Hockaday 1978 : mean change and range reported, but no variance or exact P values reported; authors not contacted due to publication date of study
Change in body weight (kg) at ≥ 12 months	Hockaday 1978 : mean change and range reported, but no variance or exact P values reported; authors not contacted due to publication date of study
Number of participants per group with weight loss of at least 5% at ≥ 12 months	None
Cardiovascular mortality at ≥ 12 months	None
Change in HbA1c (%) at ≥ 12 months	Samaha 2003 : mean change and standard deviation reported, but numbers of participants per trial arm not reported; authors unresponsive
Change in DBP (mmHg) at ≥ 12 months	None
Change in LDL cholesterol (mmol/L) at ≥ 12 months	None

Table 5. Trials without usable data for outcomes in Summary of findings tables in Comparisons 3 and 4 (Continued)

Constipation at three to < 12 months	Saslow 2017a: Data captured using an adaptation of the Health Symptom Checklist at 3 months; reported that participants in low-carbohydrate diet group experienced increased constipation (mean change of 0.4, P = 0.03); no data reported for balanced-carbohydrate diet group; data not provided when authors contacted

Table 6. Overview of Synthesis and Included Studies (OSIS)

Study name (year); country of conduct	Other key detail of intervention (trial duration; extent of carbohydrate restriction; energy prescription between groups; exercise component included; what materials, when and how much was provided)	Population (sample size: intervention/control numbers randomised)	Outcome domains with available data	Specific outcomes measured and reported	Time point of measurement	Method of synthesis
Comparison 1 - Population and diet phase: People without T2DM; weight-reducing phase only						
Aude 2004	12 weeks; incremental carbohydrate restriction; different energy prescription; no exercise component; written diet guidelines and counselling every two weeks (1 hour initially and 30 minute sessions thereafter) provided	Women & men (n = 30/30)	Change in body weight	1. Short-term change in body weight	1. 12 weeks	1. MA
Bales 2017	6 months; low-carbohydrate; similar energy prescription; no exercise component; individualised calorie prescription and meal plans, two individual counselling sessions and weekly group sessions thereafter provided to both groups - additionally, pre-portioned lean meat provided to the intervention group	Women (n = 51/29)	Change in body weight	1. Short-term change in body weight	1. 6 months	1. MA
Bazzano 2014	52 weeks; very low-carbohydrate; ad libitum energy prescription; no exercise component; recipes, sample menus, food and shopping lists, meal planners and guides, one meal replacement per day, weekly individual counselling sessions (1 hour) for the first four weeks, biweekly group sessions for five months thereafter and monthly sessions for the last six months, provided	Women & men (n = 75/73)	Change in body weight Change in blood pressure Change in blood lipids Participant-reported	1. Short-term change in body weight 2. Long-term change in body weight 3. Long-term change in DBP 4. Long-term change in SBP 5. Long-term change in LDL-c 6. Long-term change in HDL-c 7. Long-term change in TC	1. 6 months 2. 12 months 3. 12 months 4. 12 months 5. 12 months 6. 12 months 7. 12 months	1. MA 2. MA 3. MA 4. MA 5. MA 6. MA 7. MA 8. MA 9. MA 10. MA 11. MA

				22. Long-term fatigue	22. 12 months	
				23. Short-term headaches	23. 6 months	
				24. Long-term headaches	24. 12 months	
Benassi-Evans 2009	52 weeks; low carbohydrate; similar energy prescription; no exercise component; food checklists and individual fortnightly clinic visits in the weight-loss phase (12 weeks) provided	Men (n = 16/17)	Change in body weight	1. Short-term change in body weight 2. Long-term change in body weight	1. 12 weeks 2. 52 weeks	1. MA 2. MA
Brehm 2003	6 months; very low-carbohydrate; different energy prescription; no exercise component; test kits for ketosis, cooking tips, food diaries, pedometers and biweek-	Women (n = 26/27)	Change in body weight	1. Short-term change in body weight	1. 6 months	1. MA

Table 6. Overview of Synthesis and Included Studies (OSIS) (Continued)

	ly group meetings, alternated with individual meetings, were provided					
Brehm 2005	4 months; very low-carbohydrate; different energy prescription; no exercise component; food records, pedometers and weekly counselling sessions, alternating between group (1 hour) and individual (30 minute) sessions each week, for the first half of the study were provided	Women (n = 25/25)	Change in body weight	1. Short-term change in body weight	1. 4 months	1. MA
Calleja-Fernández 2012	1 year; low-carbohydrate; similar energy prescription; no exercise component; written materials, daily food diary and counselling visits every two weeks for 16 weeks, and every third month thereafter, provided	Women & men (n = 21/19)	Change in body weight Change in blood lipids	1. Short-term change in body weight 2. Long-term change in body weight 3. Short-term change in BMI 4. Long-term change in BMI 5. Long-term change in LDL-c 6. Long-term change in HDL-c 7. Long-term change in TC 8. Long-term change in TG	1. 16 weeks 2. See Table 4 3. 16 weeks 4. 12 months 5. 12 months 6. 12 months 7. 12 months 8. 12 months	1. MA 2. NR 3. MA 4. MA 5. MA 6. MA 7. MA 8. MA
Cornier 2005	16 weeks; low-carbohydrate; similar energy prescription; no exercise component; prepared foods for all meals and weekly meetings provided	Women (n = 11/10)	Change in body weight	1. Short-term change in body weight	1. 16 weeks	1. MA
Dyson 2007	24 months (3 months active weight loss); very low-carbohydrate; similar energy prescription; exercise component included; recipe booklet and sessions for three months provided	Women & men (n = 6/7)	Change in body weight	1. Short-term change in body weight 2. Short-term change in BMI	1. 3 months 2. 3 months	1. MA 2. MA
Ebbeling 2007	18 months; low-carbohydrate; ad libitum energy prescription; exercise component included; food choice lists, cooking demonstrations, 23 group workshops (1 hour each, six in the first two months and monthly thereafter), one initial private counselling (1 hour) followed by five monthly	Women & men (n = 36/37)	Change in body weight Change in blood pressure	1. Short-term change in body weight 2. Long-term change in body weight 3. Long-term change in DBP 4. Long-term change in SBP	1. 26 weeks 2. 74 weeks 3. 18 months 4. 18 months	1. MA 2. MA 3. MA 4. MA 5. MA 6. MA

Table 6. Overview of Synthesis and Included Studies (OSIS) (Continued)

	motivational phone calls (30 minutes each) provided		Change in blood lipids	5. Long-term change in LDL-c 6. Long-term change in HDL-c 7. Long-term change in TG	5. 18 months 6. 18 months 7. 18 months	7. MA
Farnsworth 2003	68 weeks (12 weeks active weight loss); low-carbohydrate; similar energy prescription; no exercise component; fixed-menu plans, key foods making up 60% of the diet and sessions in two week intervals over 16 weeks provided to both groups - additionally, low-fat cheese and skim milk powder provided to the intervention group	Women & men (n = 33/33)	Change in body weight	1. Short-term change in body weight	1. 12 weeks	1. MA
Foraker 2014	52 weeks; low-carbohydrate; similar energy prescription; exercise component included; pedometer and weekly counselling sessions (individual or telephonic) for the first month, then every three weeks until the fourth month and every six weeks thereafter, provided	Women (n = 38/41)	Change in body weight Change in blood pressure Change in blood lipids	1. Short-term change in body weight 2. Long-term change in body weight 3. Long-term change in DBP 4. Long-term change in SBP 5. Long-term change in LDL-c 6. Long-term change in HDL-c 7. Long-term change in TC	1. 34 weeks 2. 52 weeks 3. 52 weeks 4. 52 weeks 5. 52 weeks 6. 52 weeks 7. 52 weeks	1. MA 2. MA 3. MA 4. MA 5. MA 6. MA 7. MA
Foster 2003	12 months (only first 6 months eligible as low-carbohydrate); incremental carbohydrate restriction; different energy prescription; no exercise component; books of the relevant diet, an initial individual meeting and follow-up meetings at three and six months (15 to 30 minutes each) provided	Women & men (n = 33/30)	Change in body weight	1. Short-term change in body weight	1. See Table 4	1. NR
Foster 2010	2 years (only first 6 months eligible as low-carbohydrate); incremental carbohydrate restriction; different energy prescription; exercise component included; diet guidelines and group sessions (75 to 90 minutes) every other week for 20 weeks, and monthly thereafter provided	Women & men (n = 153/154)	Change in body weight Participant-reported	1. Short-term change in body weight 2. Short-term constipation 3. Short-term halitosis	1. 6 months 2. 6 months 3. 6 months	1. MA 2. MA 3. MA

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

Table 6. Overview of Synthesis and Included Studies (OSIS) *(Continued)*

				adverse events		
Frisch 2009	12 months; low-carbohydrate; similar energy prescription; no exercise component; ambulatory training, diet books, electronic scale and weekly individual (telephonic) counselling sessions provided	Women & men (n = 100/100)	Change in body weight	1. Short-term change in body weight	1. 6 months	1. MA
				2. Long-term change in body weight	2. 12 months	2. MA
			Change in blood pressure	3. Short-term change in BMI	3. 6 months	3. MA
				4. Long-term change in BMI	4. 12 months	4. MA

				10. Long-term change in TG	10. 12 months	10. MA

Table 6. Overview of Synthesis and Included Studies (OSIS) (Continued)

Goni 2018	4 months; low-carbohydrate; similar energy prescription; no exercise component; information on feeding schedules, portion sizes and cooking methods as well as counselling sessions for 16 weeks provided	Women & men (n = 72/75)	Change in body weight Participant-reported adverse events	1. Short-term change in body weight 2. Short-term change in BMI 3. Short-term depressive symptoms 4. Short-term anxiety symptoms	1. 16 weeks 2. 16 weeks 3. 16 weeks 4. 16 weeks	1. MA 2. MA 3. MA 4. MA
Griffin 2013	12 months; low-carbohydrate; similar energy prescription; exercise component included; kitchen scales, checklists, recipe ideas, vouchers (at baseline, three, six, nine and 12 months) and weekly counselling sessions for three months, fortnightly sessions from three to six months and monthly sessions thereafter, provided	Women (n = 36/35)	Change in body weight Change in blood lipids	1. Short-term change in body weight 2. Long-term change in body weight 3. Long-term change in LDL-c 4. Long-term change in HDL-c 5. Long-term change in TC 6. Long-term change in TG	1. 6 months 2. 12 months 3. 12 months 4. 12 months 5. 12 months 6. 12 months	1. MA 2. MA 3. MA 4. MA 5. MA 6. MA
Haufe 2013	23 to 42 months (6 months active weight loss); low-carbohydrate; similar energy prescription; no exercise component; weekly group sessions and individual sessions every two months provided	Women & men (n = 33/33)	Change in body weight	1. Short-term change in body weight 2. Short-term change in BMI	1. 6 months 2. 6 months	1. MA 2. MA
Jesudason 2013	24 months; low-carbohydrate; similar energy prescription; no exercise component; sample food packs or monetary vouchers (baseline, 12 and 26 weeks), protein counter, checklist, monthly group education and support sessions for the first six months, and every three months thereafter, and monthly individual or telephonic counselling provided	Women (n = 164/159)	Change in body weight	1. Long-term change in body weight	1. 24 months	1. MA
Josse 2011	16 weeks; low-carbohydrate; similar energy prescription; exercise component included; individualised eating plans, two study drinks per day, all dairy products, measuring cups and spoons, energy expenditure device, and biweekly private (individual or small-group) counselling sessions provided	Women (n = 31/31)	Change in body weight	1. Short-term change in body weight 2. Short-term change in BMI	1. 16 weeks 2. 16 weeks	1. MA 2. MA

Table 6. Overview of Synthesis and Included Studies (OSIS) (Continued)

Juanola-Falgarona 2014	6 months; low-carbohydrate; similar energy prescription; no exercise component; leaflet with general dietary recommendations, menus, seasonal receipts, access to an informative website, and individual counselling sessions at baseline and two weeks, monthly thereafter, provided	Women & men (n = 41/40)	Change in body weight	1. Short-term change in body weight 2. Short-term change in BMI	1. See Table 4 2. 6 months	1. NR 2. MA
Keogh 2007	52 weeks (12 weeks active weight loss); low-carbohydrate; similar energy prescription; no exercise component; counselling sessions every two weeks provided	Women & men (n = 36 in total, per group NR)	Change in body weight	1. Short-term change in body weight	1. 12 weeks	1. MA
Kitabchi 2013	6 months; low-carbohydrate; similar energy prescription; no exercise component; individualised weekly food diary as well as fresh, prepackaged and frozen foods, shakes and meal bars, and weekly visits provided	Women (n = 14/18)	Change in body weight	1. Short-term change in body weight 2. Short-term change in BMI	1. See Table 4 2. 6 months	1. NR 2. MA
Klemsdal 2010	12 months; low-carbohydrate; similar energy prescription; no exercise component; dietary suggestions and recipes, as well as individual (baseline, week two, months one and nine) and group (at month two, three, four five and six) counselling sessions provided	Women & men (n = 100/102)	Change in body weight Change in blood pressure Change in blood lipids	1. Short-term change in body weight 2. Long-term change in body weight 3. Long-term change in DBP 4. Long-term change in SBP 5. Long-term change in LDL-c 6. Long-term change in HDL-c 7. Long-term change in TC 8. Long-term change in TG	1. 6 months 2. 12 months 3. 12 months 4. 12 months 5. 12 months 6. 12 months 7. 12 months 8. 12 months	1. MA 2. MA 3. MA 4. MA 5. MA 6. MA 7. MA 8. MA
Landers 2002	12 weeks; very low-carbohydrate; different energy prescription; no exercise component; diet materials, sample menus, carbohydrate counting booklets, exchange lists, food diaries and individual weekly counselling meetings provided	Women & men (n = 28/33)	Change in body weight	1. Short-term change in body weight	1. 12 weeks	1. MA
Lasker 2008	4 months; low-carbohydrate; similar energy prescription; exercise component included; menu plan with meals, electronic food	Women & men (n = 32/33)	Change in body weight	1. Short-term change in body weight	1. 4 months 2. 4 months	1. MA 2. MA

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

Table 6. Overview of Synthesis and Included Studies (OSIS) (Continued)

	scales, accelerometers and weekly group meetings (1 hour) provided			2. Short-term change in BMI		
Layman 2005	4 months; low-carbohydrate; similar energy prescription; no exercise component; two-week menu plans, food scales and weekly group sessions (1 hour) provided	Women (n = 12/12)	Change in body weight	1. Short-term change in body weight	1. 16 weeks	1. MA
Layman 2009	12 months; low-carbohydrate; similar energy prescription; exercise component included; menu plans, electronic food scales, armband accelerometers, and weekly counselling sessions (1 hour) provided	Women & men (n = 64/66)	Change in body weight Change in blood lipids	1. Short-term change in body weight 2. Long-term change in body weight 3. Long-term change in LDL-c 4. Long-term change in TG	1. 4 months 2. 12 months 3. See Table 4 4. 12 months	1. MA 2. MA 3. NR 4. MA
Lean 1997	6 months; low-carbohydrate; similar energy prescription; no exercise component; written materials on the relevant diet, recipes, certain foods to support compliance, six-weekly sessions, and telephone contact to reduce attrition provided	Women (n = 53/57)	Change in body weight	1. Short-term change in body weight 2. Short-term change in BMI	1. 6 months 2. 6 months	1. MA 2. MA
Lim 2010	15 months; very low-carbohydrate; similar energy prescription; no exercise component; meal plans, recipe information as well as uncooked, pre-weighed key foods and dietary counselling, every two weeks for the first three months and at month three, six, nine, twelve and 15 thereafter, provided	Women & men (n = 30/30)	Change in body weight Change in blood pressure Change in blood lipids	1. Short-term change in body weight 2. Long-term change in body weight 3. Long-term change in DBP 4. Long-term change in SBP 5. Long-term change in LDL-c 6. Long-term change in HDL-c 7. Long-term change in TC 8. Long-term change in TG	1. 3 months 2. 15 months 3. 15 months 4. 15 months 5. 15 months 6. 15 months 7. 15 months 8. 15 months	1. MA 2. MA 3. MA 4. MA 5. MA 6. MA 7. MA 8. MA
Liu 2013	12 weeks; incremental carbohydrate restriction; different energy prescription; no exercise component; all meals, and daily monitoring of intake provided	Women (n = 25/25)	Change in body weight	1. Short-term change in body weight 2. Short-term change in BMI	1. 12 weeks 2. 12 weeks 3. 12 weeks 4. 12 weeks	1. MA 2. MA 3. MA 4. MA

Low-carbohydrate versus balanced-carbohydrate diets for reducing weight and cardiovascular risk (Review)

			Change in blood glucose			
Larsen 2011	12 months (9 months of weight maintenance); low-carbohydrate; similar energy prescription; exercise component included; five individual sessions (2.5 hours), and group sessions (3.3 hours) every three months provided	Women & men (n = 57/51)	Change in body weight	1. Long-term change in body weight	1. 12 months	1. MA
				2. Long-term change in DBP	2. 12 months	2. MA
				3. Long-term change in SBP	3. 12 months	3. MA
				4. Long-term change in HbA1c	4. 12 months	4. MA
				5. Long-term change in LDL-c	5. 12 months	5. MA
				6. Long-term change in HDL-c	6. 12 months	6. MA
				7. Long-term change in TC	7. 12 months	7. MA
				8. Long-term change in TG	8. 12 months	8. MA
Sato 2017	18 months (12 months of weight maintenance); low-carbohydrate; different energy prescription; no exercise component; one individual session provided	Women & men (n = 33/33)	Change in body weight	1. Long-term change in body weight	1. 18 months	1. MA
				2. Long-term change in BMI	2. 18 months	2. MA
				3. Long-term change in HbA1c	3. 18 months	3. MA
				4. Long-term change in LDL-c	4. 18 months	4. MA
				5. Long-term change in HDL-c	5. 18 months	5. MA
				6. Long-term change in TG	6. 18 months	6. MA
Watson 2016	24 weeks (12 weeks of weight maintenance); low-carbohydrate; similar energy prescription; exercise component included; core study foods, and dietary advice sessions every two weeks provided	Women & men (n = 32/31)	Change in body weight	1. Short-term change in body weight	1. 24 weeks	1. MA
				2. Short-term change in BMI	2. 24 weeks	2. MA

BMI,
 DBP, diastolic blood pressure
 HbA1c,
 HDL-c, high density lipoprotein-cholesterol
 LDL-c, low density lipoprotein-cholesterol
 MA, meta-analysis
 NR, not reported
 SBP, systolic blood pressure

T2DM, type 2 diabetes mellitus
TC, total cholesterol
TG, triglycerides

HISTORY

Protocol first published: Issue 5, 2019

CONTRIBUTIONS OF AUTHORS

CN and AB drafted the review and AS, KN, MR and JV provided inputs to finalise the review.

DECLARATIONS OF INTEREST

CN: Celeste is partly supported by the Research, Evidence and Development Initiative (READ-It). READ-It (project number 300342-104) is funded by UK aid from the UK government; however, the views expressed do not necessarily reflect the UK government's official policies. No known conflicts of interest.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

We added the outcome, change in weight at three to < 12 months, to the list of outcomes for inclusion in the summary of findings tables. After inputs from clinicians, recent studies and people wanting to follow weight-reduction diets, we considered short-term weight reduction to be a clinician- and patient-important outcome.

We included four comparisons instead of two as stated in the protocol. This was done in order to separate findings where people implemented only an active weight-reducing phase of the diets, from findings where people implemented a weight-reducing phase followed by weight-maintenance phases of the diets (periods where initial diet prescriptions or advice changed to indicate less focus on active weight reduction, for example, changes in energy prescriptions or no restrictions on carbohydrate intake).

We changed one of the sensitivity analyses from "attrition bias (i.e. first pool all relevant studies per outcome, and then pool only studies with < 15% missing data from the total initial sample)" to "first pool all relevant studies per outcome, and then pool only studies with low or some concerns for bias due to missing outcome data (domain 3 in the Cochrane Risk of Bias 2 tool)."

We excluded the adherence assessment detailed in our protocol as we did not deem it relevant for a review aiming to assess assignment to intervention.
