22 **Article text**

23 More than 16,000 cases of monkeypox have been reported globally in 2022, predominately  
24 in non-endemic countries [1]. Although transmission in the current outbreak is typically via  
25 prolonged direct contact with confirmed cases, infection-competent monkeypox virus  
26 (MPXV) has been recovered from contaminated environments multiple days after last  
27 occupancy [2] raising the potential for fomite transmission. In addition, prolonged close  
28 contact such as working in an open-plan office could result in respiratory droplet  
29 transmission of MPXV [3,4].

30 In May 2022, an individual working in a non-clinical role in an administrative office within a  
31 hospital acquired MPXV infection following non-occupational exposure. The individual  
32 worked in a 15-desk open-plan office for one working day following onset of a mild,  
33 influenza-like illness, and took steps to reduce mixing and avoid close contact with others.  
34 Several COVID-19 control measures were still implemented within this office including a  
35 requirement to wear medical masks and regular hand hygiene. In addition, this office had  
36 permanent desk partitions between desk spaces. The individual reported skin lesions  
37 appeared two days after taking sickness absence at which point the office was closed to all  
38 staff pending a risk assessment and risk management plan. 17 staff contacts were identified,  
39 including six category 2 and four category 1 contacts according to UKHSA categorisation [5];  
40 four individuals accepted post-exposure prophylaxis with Imvanex<sup>®</sup> vaccine when offered in  
41 accordance with UKHSA guidelines. No contacts developed symptoms consistent with  
42 monkeypox during their 21-day monitoring periods.

43 A decision to clean and decontaminate the office was made given its location within a  
44 healthcare facility and due to the environmental stability of orthopox viruses. This was

45 performed by professional decontamination staff following a protocol used during previous  
46 monkeypox outbreaks [6]. The hospital performed a final decontamination of the office  
47 using hydrogen peroxide vapour (Bioquell BQ-50 with 35% hydrogen peroxide solution).

48 Prior to decontamination, environmental sampling was performed to identify MPXV  
49 contamination. Sampling occurred four days after the case was last in the office and two  
50 days after office closure. Surface samples were collected from non-porous surfaces such as  
51 desks and telephones using Copan UTM® swabs, and from porous surfaces such as carpets  
52 and chair seats using the Sartorius MD8 Airport with gelatine filters. In addition, SKC  
53 wearable samplers were utilized during the sample collection process to measure any re-  
54 aerosolisation of MPXV. All samples were processed as previously described [7] and  
55 analysed for the presence of MPXV DNA using qRT-PCR as previously reported [2,8].

56 Only 3/34 surface samples were positive for the presence of MPXV DNA with all positive  
57 samples returning crossing threshold (Ct) values indicating low-level contamination (Figure  
58 1). All three positive samples were from the case's desk area including their telephone (Ct  
59 37.7), keyboard (Ct 36.9) and a 10x10cm area of their desk (Ct 34.3). Five other surface  
60 samples from the case's desk were negative for MPXV DNA as were 26 surface samples  
61 collected from other desks and high-touch areas throughout the office. All non-porous  
62 samples were negative for MPXV DNA, as were both wearable samples.

63 Virus isolation was attempted on the Ct 34.3 positive desk sample using a previously  
64 described method [7]; no evidence of replicating virus or cytopathic effect was observed  
65 after 10 days of monitoring suggesting the absence of infection-competent virus. As  
66 sampling was performed four days after occupancy by the infected individual, it is possible  
67 that some level of DNA or viral degradation occurred prior to sampling, although the office

68 was windowless (minimising UV light degradation), was not cleaned prior to sampling, and  
69 MPXV is known to be environmentally stable.

70 It is notable that the patient reported skin lesions only emerged after they had taken leave  
71 from work due to illness, raising the possibility that the MPXV DNA detected may have come  
72 from respiratory secretions through droplets or contaminated hands. If so, it is possible that  
73 their use of a medical mask may have reduced environmental contamination by respiratory  
74 droplets containing virus.

75 Although this office may be similar to other offices in design, our findings should be seen as  
76 context-specific, including that the individual worked only during the early 'prodromal' phase  
77 of their monkeypox illness, several COVID-19 measures were still in place, and physical  
78 partitions were present between desk spaces. The limited detection of MPXV DNA and  
79 absence of secondary cases do not demonstrate that cleaning is unnecessary in an office  
80 where an infected person has worked, or that focussed cleaning of an infected person's desk  
81 area is sufficient. In the absence of real-time environmental sampling to inform  
82 decontamination, and the fact that the office was within a hospital, our detection of  
83 environmental MPXV DNA supports the decision made to remediate the entire office. These  
84 data confirm that MPXV contamination can occur in workplace environments occupied by a  
85 person with early monkeypox illness and, accordingly, appropriate cleaning and  
86 decontamination measures should be considered in such situations.

105 Funding: This work was funded by UKHSA Grant in Aid funding and the NIHR Health  
106 Protection Research Unit in Emerging and Zoonotic Infections. The funding source had no  
107 involvement in study design; in the collection, analysis and interpretation of data; in the

108 writing of the report; or in the decision to submit the article for publication. JD is supported  
109 by the Moh Foundation.

110 Competing interests: None declared.

111 Ethical approval: The investigations performed were a component of the urgent public  
112 health investigation performed as part of UKHSA's public health incident response to cases  
113 of a high consequence infectious disease in the UK. UKHSA is the national health security  
114 agency for England and an executive agency of the UK Government's Department of Health  
115 and Social Care. The study protocol was subject to internal review by the Research Ethics  
116 and Governance Group, which is the UKHSA Research Ethics Committee, and was granted  
117 full approval.
